JS,
I may be misreading your post, excuse me if I am. But, how are arcing power transformers a part of a fireman's job, other than putting out any resulting fire? They certainly can't, and shouldn't try to repair them. And I don't know how they could turn one 'off', do you? Referring any complaints to the power company responsible for that arcing transformer is about all they can do. Expecting the Fire Department to 'fix' it is a little unreasonable.
- 'Doc

Ever owned a commercial building? Ever have the local FD do their annual inspection on it? Ever see a building closed to access because the FD has found it to be a fire hazard and has ordered corrections/demolition?

Whose responsibility do you think fire hazards with the potential to do major property damage to citizens and/or homes/businesses is?

You ever seen one of those xfrmrs explode releasing the oil inside? Gallons of burning oil begin released in a hurry is not only a serious danger to structures, it would do serious damage to pedestrians, etc.

Would you report it to the police? (well, possibly, but who do you think they would call?) The dog catcher? The coroner? The mayor? A high school principal? The local boy scout master? Well maybe, but here in California, I am pretty sure the responsibility would lie with the FD ...

You are joking with such a question, right?

Regards,
JS

FD "fix" the xfrmr? (well, in a round-about-way, YES! EXACTLY!)

Again, you are joking right?

Logic dictates they would call the power company whose
property/responsibility the xfrmr is and tell them it is SERIOUS fire
hazard which they cannot ignore ... and that would carry a LOT MORE
WEIGHT than "joe blow amateur" saying he had noise on his receiver.

But then, you already knew that ... silly!

Regards,
JS

4. Re: Rigexpert AA-200 antenna analyser

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-01 09:59:58 UTC

Message-ID: <oenak.160024$Ek2.15755@newsfe17.ams2>
Source record: 24578

I've had my RigExpert AA-200 for a few weeks now and I'm impressed with it.
I have only had the MFJ-259 as a comparison.
This Analyser for what I use it for, is far superior to the MFJ-259 in all ways. This is just what I have experienced myself.. Others may prefer the MFJ. I can't think why though.
Using a small homebrew loop coupler to measure the frequency of my homebrew traps on the AA-200 was very consistent and repeatable, with the same reliable and accurate readings every time. I got a fantastic dip at resonance. Unlike my TR Dip meter and the MFJ-259. Both would be close each time but not spot on like the AA-200.
I found using the AA-200 for homebrew Antennas is very easy and nice to use.
I'm new to using Analysers , so I'm still learning. But I can't fault this Analyser in any way for what I use it for. It does every thing I want it to do and does it very well indeed, all the time and every time with out fail.
What amazes me is after using the MFJ-259 and the AA-200 is why people are still buying the MFJ. I know its cheaper, but after having two fail on me, well never again.

Message-ID: <486A24C9.4060504@nosspam.activ8.net.au>
Source record: 24579

Q. What is the optimum antenna type to give the maximum gain given a fixed overall length of elements? Or, alternately, what's the minimum amount of wire/tubing to give a specified gain? (Neglecting support structures)
As an example, for a gain of 15 dBi, an 11 element Yagi appears to have about the same gain as two stacked 6 element Yagis which collectively use one more element. But what about collinears, V Beams, arrays of different sized Yagis etc. etc.?
Just out of curiosity.

Alan

a parabolic reflector fed with a feedhorn. no 'elements', just a hole in a pipe and a big curved plate. you need to define the parameters a bit more. for instance with no reflectors or directors, just driven verticals you can make lots of gain. phased array radars have no wire/tubing elements, just holes in a plate each with its own transmitter/receiver. and how do you count dishes, corner reflectors, and the ground? by changing the height of an antenna you can drastically change the gain at some particular takeoff angle, so maybe you want to restrict it to free space. an do you want minimum element count, or total material length? a very long wire can create high gain lobes, but may not be very useful if you are thinking of something rotateable.

Have I ever seen... etc? Yes, I have. About the exploding
transformers, Fir Marshals, most of the other thingys too. Just
depending on where you live, a Fire Marshal usually does have quite a
bit of authority to recommend things. Same conditions, most places do
not allow that Marshal to have a "My word is final." authority.
That's usually reserved for the judicial system, except in cases of -
immediate- life/death circumstances. The case of that noise
transformer just doesn't fall into tha catagory, sorry 'bout that.
How do I know all that? Cuz I worked around that sort of thingy for 20
years.
- 'Doc

Than that explains it; you just failed to read/comprehend the first post which began this thread ...

The danger he stated was not a "noise transformer", he said, and I quote here, "I live in town, three blocks from a failing transformer. At night you can see it arcing continuously. ..."

While it is true, the first, above ("noise transformer"), is not a serious danger involving the FD--the second surely is ("failing transformer"--"arcing continuously.")

Hello Alan,

There is no optimum antenna design that fits everything. Some factors:
Center Frequency
Side lobe level requirements
Gain requirements
Available materials
Required bandwidth.
Design skills / Experience
Ease of production
Number of antennas to be produced,
Available volume
Sentimental
Environmental aspects
Visibility (think of covert antennas).

There are (physical) limitations on antenna gain and antenna size.
Antennas with high gain must have a size far above wavelength.
Reduction of side lobes with given gain also requires a larger
antenna.

Omni directional gain requires large vertical antenna structures.
Every 3 dB gain increase, requires double the (vertical) size.

Best regards,

Wim

May I offer a rebuttal to your use of "size:" with respect to
radiators?
The addition of radiators and a time varying field to a Gaussian field
shows that a radiator can be any size,shape or elevation as long as it
is in equilibrium.
This is because the result of additions to Gauss's static law results
in the same law of Maxwell.
It can also be seen that any deviation from a straight line format
which creats lumped loading must be neutralized since
radiation is related to distributed loads L and C. Thus shape or size
is a determination of the neutralisation of lumped loads
while attaining equilibrium. With the above in hand it can be seen
that Foucault current generates a field that elevates particles that
have attained a weak magnetic field by entering the earths system
which provides for their rejection or ejection. Per Newtons Law the
weak forces
involved (Fermi) create an oscillation of the radiator which is a
mirror image of arriving impulses upon a radiuator with the same
natural resonance.
It is only convention that calls for an radiator to be straight of
which a helix antenna is an excellent example ,where a continuation of
rotation back to the originating point provides for a full circuit in
equilibrium si9nce added lumped loads are cancelled. Examples of the
foucault current was provided earlier on this forum when describing
the separation of scrap metal by Foucault current rejection. As with
Newton, Faraday Gauss etc all laws depend on the theme of equilibrium
within a boundary of a balanced universe and not on minute sections
thereof.
Have a great week end
Art

Art:

This mysterious "equilibrium" (which I seem to have a bit of problem
getting my mind wrapped about), although you, seemingly, sum up a group
of properties with a single word, isn't this just "resonance"--with
respect to conductor length/width, capacitance to surrounding objects
and the shape/form of the magnetic field produced by antenna currents, etc?

However, a thought did come to my mind ... with the new technique of
"taking pictures" of light waves/particles--if a super-strong
electromagnet was pulsed in an enclosure of excitable gas(es), perhaps

we could see some unknown/yet-unseen phenomenon ...

However, you are speaking of resonance, aren't you? <still-scratching-head>

Regards,
JS

no, he's not... its the cosmic equilibrium between his fictitious particles and the attraction of them the diamagnetic materials that makes antennas work... of course he can't explain why ferromagnetic materials also work as antennas, but that hasn't stopped him from spewing his garbage all over this group. if you keep scratching your head while you try to figure out what he is talking about you will run out of hair before you even get to first base.

I was considering a similar problem recently and the thing that came
to mind was adapting bits and pieces of an Yaesu Atas system to a
rotator motor. FWIW.

No. Resonance is a quality of equilibrium but equilibrium is not
necessarily a part of resonance.
For instance, a full wavelength corresponding to a period of
oscillation is a form in equilibrium
where as a fractional wavelength can be resonant but certainly in
equilibrium
This really ia at the bottom of Newtons law regarding action and
reaction where all forces around a point
must equal zero. For instance if we have a member that is carrying an
alternating current applying such law states that there is
no moving charge on the inside of the member and where all charges on
the surface are in static form. The same law is used to determine the
likes oif skin depth.Now I have a problem with fractional WL current
carrying members where the surface charges move to one end which
suggests a internally moving charge. This effect can be seen when
comparing a dipole with a quad where the dipole can create corona at
the ends as the charges pile up as they look for a place to go doing
the time space of one period
where as a quad is a full WL anmd in equilibrium.
Maxwells law is based on equilibrium which means it can accoun t for
what is known as the "week force" which Einstein searched for in vain
for his GUT theory., Its inclusion in the laws of the masters was by
mathematical derivitation where they could not devine it even tho it
is one of the basic four forces of the Universe, the CLASSICAL model.
Now with my adaptation of gauss';s law which provides a picture of
radiation the appearance of weak eddy currents give rise to this
unknown weak force. With computers which are based around equilibrium
and Maxwell and now my extension of Gaussian law will provide the
result of that weak force by placing a radiator tipped from right
angles to the earths surface since all inside of a gaussian field MUST
be in equilibrium. If you need more explanation just ask for it or get
hold of a physics professor who is not a ham!

Actually, there is only one alternative--the ether ... something which I
wish they will explore with new techniques ... Something (ether) which
even Einstein acknowledged. However, why Art would "waltz" around
something which is already being explored/argued, and cloak that
"waltzing" in an unfamiliar term(s) is simply beyond me ... unless ones'
point is obsfucation.

Would a section of 1/2" copper pipe work as a good choke? Simply slid over the coax?

I've seen lightning chokes where about a 8ft piece of copper pipe was slide over coax to choke off a lightning surge.

Hmmm ... sounds to me of the magnetic component of the antenna current reacting with, or acting upon, the ether and creating the rf wave phenomenon (waves/particles/etc.) ... there are a millions ways, perhaps, to refer to this, as yet unproven effect/affect, but this theory has already been on the table for centuries ... discarded and then reincarnated at least once ...

I have had excellent results with eliminating urban near field RF noise
with loop antennas such as my T2FD. Went from s7 noise floor to almost
nothing. Desirable signals went from S7 to S6, but S7 in a S7 noise floor
is not anywhere usable as a S6 in a near quite noise floor!

Also, if the arc is visible on the xformer, I'd call the fire dept

If the pipe was attached at the outside of the coax, at the antenna feed and have a length of 1/4, 1/2 wavelength, etc. (depending on antenna type/length), I would suspect it would be an "easier" path for the rf currents which were flowing on the outside of the coax, and they would now choose the path of the pipe--wouldn't you? However, another way of looking at this particular situation would be you just added another element to the antenna!

However, I suspect you are suggesting chucking that (1/4?) wavelength of pipe over the coax an no specific point and with no direct connection to the coax; and, in that case, I would have to experiment, do research or ask someone with experience ... however, I suspect not ...

Jim
You are now doing your job as a teacher and a ham not a physicist.
The first two jobs are about repeating what is in the books parrot
fashion
and to prevent change . A physicist, which you are not, accepts
the
possibility that all is not known and is willing to question or debate
a
subject instead of exercising free speech without substance.
Using what education you have on the subject state in clear terms as
to why
what you are refering to is ridiculous so your posts have some meaning
that
others can follow inteligently
Regards
Art

What part the ether being acknowledged by Einstein? Colleges, papers, physicists exploring the existence/properties of the ether? What? You can't read? You can't use Google? You missed my posts quoting Einsteins last mention of the ether? Help me out here ...

> For my part everything that I have stated can be proven and known to
> exist

I would even accept the arrls' material is what "really exists" (this material will only need to be revised if and when the existence of the ether can be known for certain and its' properties exploited though new designs--mostly.) And, is in line with all presently accepted theory--up to the point where the discussions begin of whether light (and therefore rf) is composed of waves and/or particles or some phenomenon which exhibits both of these characteristics but is separate in existence, in some way. AND, whether rf/light "shoots" across a true "nothing" or "strikes the chords of the ether" and transverses a media which we can not see and know its properties, yet?"

What? You are introducing a "third theory" which does not deal with shooting photons and nothing (well, you can shoot light waves through gases and glass, obviously!), or waves and a media?

It would seem to me your "equilibrium" must either deal with a "nothing" or an ether ...

In my mind, all antenna theory revolves around a few simple truths:

1) The antennas ELECTRICAL length relates DIRECTLY to what frequencies it is efficient at.

2) Antennas are subject to laws of ac resistance.

3) Antennas are subject to knows laws of inductance.

4) Antennas are subject to know laws of capacitance.

5) All of the above, in one form or another, contribute to and define an antenna impedance.

Some of us just wonder if the ether exists, and whether knowing its' properties, if so, might give one a break through into antenna designs not yet even though of ...

> It is the hands of most hams who are interest in antenna programs to
> follow
> the trail that I point to with respect to arrays in equilibrium for

Except for a few hams, most notable Cecil, Richard Clark, Walter Maxwell, etc., most are the "appliance users" and/or "brass pounders of yesteryear." What remains is ill suited to find anything other than a rare contact on contest/field-day, or perhaps a new keying device capable of creating one more character per minute ...

You will forgive me if I examine your motives, if pure of heart, I am sure they will stand as fitting ...

No Art, I think you are confused and using an "equilibrium" to keep from coming to terms with that, or you are "obsfucating us, with intent!"

But then, I could just be confused myself ...

Regards,
JS

OK, maximum gain for a single frequency, free space, sidelobes and back-front ratio not important. Not concerned about number of elements - only minimum total material length. Doesn't need to be rotatable - this is a purely theoretical exercise.

Parabolic reflector sounds good but it's a bit hard to quantify for the purposes of minimising total material length. Perhaps one could use a wire mesh dish. Would that use more or less material than a Yagi? I would imagine that a phased array radar could use the wire mesh approach but the same questions would apply as for the parabolic reflector. Same for corner reflectors.
Arrays of driven elements may be promising but the few such antennae that I've simulated so far, use more material than Yagis for the same gain.

I think the expectation is that the fire department would be sensitive to something that has an obvious potential for starting a fire.

Fire departments also know who to talk to at the power company to get things turned off during fire emergencies, who might either be the same people who would actually care about an arcing transformer or would know who would.

Lastly, fire departments are local and easier to deal with than the FCC.

John if you have no comprehension of equilibrium you will never be
able to define aether
Equilibrium is the essence of the universe confined to an arbitary
boundary where all forces about a point equals zero.
If they were not equal zero then the boundary breaks and we break from
equilibrium untill all forces equal zero
This is what Newton means when he made the statement Every action has
an equal and opposite reaction.
Before you can even think of the so called aether then the confining
boundary of all boundaries must be determined which is where some say
GOD sits. The sun sits in its own arbitary boundary where heat
byproducts exist with the sun itself. When the position of the sun
shifts within its boundary then equilibrium is lost and equilibrium is
only then retained by removal of excess forces that detract from
equilibrium. It is commonly understood that it is nuclear byproduct
that upset equilibrium until the p-roduct is removed from within the

arbitary boundary. These are known as Neutrinos which are displaced particles with nuclear content such that they have not fully decayed. These particles when released from the arbitary border have next to zero orbital spin such that their exit is of scattered form but their numbers are in the billions per square metre. But they do have an affinity to diamagnetic materials which appears to be the most common mass of our universe. since as a substance it does not absorb free electons to rotate with said mass i.e. it rests upon the surfaces.It is these very same particles illustrated in Gaussian law of statics where the arbitary field is in equilibrium..
See. you cannot escape from the term equilibrium while in our universe but you can ignore it until equilibrium is broken and where your future is unknown. Hopefully the earths pole will move back from Siberia so that all do not have to worry.We have no people skilled in physics so there will be no debate other than the use of free speech without content

length is not a property of 'material'. mass, volume, their ratio, density,
conductivity, color, hardness, etc, are properties that can be measured.
'theoretically' the best antenna is a conductor from the source to the
receiver. a parabolic reflector can have area and thickness, therefore
volume, but the area is variable depending on how thick or thin you can make
it. any wire can be made into a parabolic reflector by smashing it thin
enough, witness the reflectors used on deep space satellites that are
extremely thin and light. or the metallic coating of a telescope mirror
that may be only a few atoms thick and yet yields tremendous gain. phased
arrays for radar get better as you remove more material from the surface
they are built from, the more holes, the better the pattern can be... so
less is more. arrays of driven elements, like the lpda, while looking
impressive and using lots of material, perform poorly at a single frequency,
but have the advantage of performing equally poorly over a wide range of
frequencies. designing antennas is a game of tradeoffs.... bandwidth for
gain, size for efficiency, gain for size, add in weight or some other
constraint like diameter and length of tubing, or dollars worth of

materials, and you add a whole new dimension. and then you need 'practicality'. as our friend art has found, you can feed parameters into an optimizer program and let it run wild and get a supergain antenna that fits in a shoebox, but try to build it and you get an air cooled dummy load... or something that only induces currents on the support structure or feedline.

the first step of engineering an antenna is to constrain the design with practical measures... frequency range, size, weight, wind load area, cost. then research possible alternative designs. then tweak the possible designs carefully to see if they can be adjusted for your specific use. but be very careful, if you suddenly find the tweaked design providing much larger gains or varying greatly from the starting point, back up and see what has happened... something is wrong. the most common problem is that someone takes a standard yagi and puts it into an optimizer and sets it for 'max gain' at one frequency, with no other constraints. the optimizer chugs along and the gain goes up, and up, and up, and up!!! but when you look at the results there are several elements bunched around the driven element and the feedpoint impedance has gone down to a fraction of an ohm. don't apply for a patent like art, throw it out and start over with more reasonable constraints. give it a range of frequencies, constrain the feedpoint impedance to a useful range, limit the element spacing, the total boom length, etc, until it gives you something slightly tweaked for your specific application but not off in left field.

Art, you are sooooo amusing. You are one of the reasons I read this group.

You make statements that haven't a shred of connection with reality, are
not testable, make statements about what you yourself have said or
"published" that aren't accurate, not even a little, and then you have
the unmitigated gaul to tell people they have said nothing.

You are wonderful!

John, my grandfather used to have some old radio books. One of them
talked about equilibriun as tunning the antenna feedlines so as to
have equal current in both lines. I can only guess that this is what
Art means.

Jimmie

David ,you have never won a debate on this newsgroup and you never
will.
You are just another Andy Cap waving hands espousing various
falsehoods.
You have never come up with anything of cosequence that was factual in
the face of disagreement. Never!
And it is too late in life for you to correct it You can still live
happilly ever after if you stop pretending you are what you are not
Your sparcity of knoweledge becomes evident as you exercise the
priviledge of free speech which is why I am a supporter of free
speech ., If you were knowledgable in the art and mathematics you
would have shown the World how a relationship between Gauss and
Maxwell could never be. If you were knowledgable in the arts you would
have explained the eddy current but again you can't. If you were
knoweledgable in antenna programs you would be aware of arrays in
equilibrium but you can't. If you were aware that radiators do not
have to be straight under Maxwellian law you would have but you cant.
If you were aware of magnetic fields that something in air you would
have mentioned it but you didn't. Fact is you do not have the
mathematics knowledge to disprove these things or the get up and go to
make an antenna in equilibrium to prove anything and the measuring of
its oscillations with respect to SWR is certainly beyond your
capability.Carry on with your free speech as I find it so
representitive of what you actually are without further investigation.
Art

The "art". So this is witchcraft? Because that is roughly what you
have been espousing your whole career on this NG.

> Maxwell could never be. If you were knowledgable in the arts you would

Spelling again. YUou must be a fast "typer".

> have explained the eddy current but again you can't. If you were
> knoweledgable in antenna programs you would be aware of arrays in

Oops, it's consistent.

> equilibrium but you can't. If you were aware that radiators do not
> have to be straight under Maxwellian law you would have but you cant.

Gee, not straight. Hmmmm. Maybe you mean like a circular thing, maybe
a wavelength in circumference?. Oh, it's a LOOP! Wow, someone ought
to investigate this possibility! It might work!

And let's see, what would happen if one folded a half wave dipole around
until it became almost a square? I think I'll call it a "Squalo"!!!

You know a guy might make a buck off these ideas, but it's just too crazy for the ham or professional radio engineering crowd, so it'll never get made. After all, we conventional types only believe in "straight" antennas.

Art, yuh gotta luv 'im.

David I have said many technical things as I see it. Nobody has given me good reason why it cannot be so
Every day false hoods are given without corroberating facts. Nobody but nobody has supplied reasonable doubt.
Now many people on this newsgroup make up stories or just lie. David a little while ago described an antenna that I made of high gain which was a result of an optimiser. One big lie! I can't model my antenna since it is made of pre twisted wire.The fact is that I am beginning to believe that many posters are not educated as they pretend they are. Computer programs abound but nobody has taken me up regarding antenna programs that I have made. Is everybody incapable or just lazy. Another point the denial of the mathematics in the dispute with respect to Gauss and Maxwell. Why was this a point of contention when no facts were supplied to deny it. Then we come to eddy curfrents and a particle rejection field. Levitation is very well known.Eddy currents are also well known and is the reason for laminations in transformers,. Why is it that such things are unknown to educated posters? Every day there is a post that suggest of an old wives tale but posters accept it without rebuttal. Why? Don,t you care about the spreading of such things? Why not a rebuttal from anybody. Why did your post stick a finger in my eye with out needed substance that pushed you to post?
Fact is that some suggest that they have an educqation without stating that it is 50 years old and they have forgotten most.
This is why many threads exceed 1000 posts. The posts have no substance in relation to the discussion at hand or attempts to change the subject. If I remember correctly Tom you were one of those who could not accept the mathematics supplied by Davis but without offering to identify errors of mathematics and still haven't.
Thank goodness for free speech so one can quickly see who they are and what they are.
Art

thats because you don't believe the proven facts, only your distorted little
view of it.

> If you were knowledgable in the art and mathematics you
> would have shown the World how a relationship between Gauss and
> Maxwell could never be.

Gauss's law is part of Maxwell's equations, they all work together and are
part of all the modeling programs that you used to like, but now claim can't
model your latest creation. and what happened to your half wave equilibrium
elements, they gone now?

> If you were knowledgable in the arts you would
> have explained the eddy current but again you can't.

as one of my past lives i wrote software for simulating eddy currents in copper or aluminum sheets for magnetic shielding of transformer vaults in hospitals. if your antennas utilize or depend on eddy currents then i understand completely why they should be classed as air cooled dummy loads.

> If you were
> knoweledgable in antenna programs you would be aware of arrays in
> equilibrium but you can't.

my arrays are very well in 'equilibrium'... except right now some of the elements are a bit bent from the winter ice so i have to go up and replace them to get the 4/4/4/4 stack on 20m back in equilibrium... right now i can hear the imbalance and it is very annoying.

> If you were aware that radiators do not
> have to be straight under Maxwellian law you would have but you cant.

right, and i have some folded and bent and circular radiators, but straight is so much easier to build.

> If you were aware of magnetic fields that something in air you would
> have mentioned it but you didn't.

say what? magnetic fields do something in the air??

> Fact is you do not have the
> mathematics knowledge to disprove these things or the get up and go to
> make an antenna in equilibrium to prove anything and the measuring of

fact is, you have presented nothing to prove what you claim besides handwaving. you can't even mathematically define equilibrium. and like the ancients you have to rely on a mysterious aether to make your warped view of the world work.

> Carry on with your free speech as I find it so

Keep in mind that as far as the fire department is concerned, that arcing transformer is already "on fire". Fire departments are trained to respond to electrical fires, which include downed power lines. That arcing transformer looks a lot like the arcing from a power line - just on a smaller scale. They work with the power companies, who have the responsibility of turning off the power, while the FD takes care of whatever extra fire that happens.

Do the immediate neighbors know the transformer is malfunctioning? Does the power company know? Not taking care of that would be gross negligence. A discreet caal to the Fire department might help, maybe even a call to the home insurance company (you'd be surprised how helpful they can be when property they insure is at risk.

In this case, definitely. There is a clear danger. The FCC is of better use when there are problems that are more nuisance than danger to the public.

47. Open Wire fed lengths

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-02 13:38:30 UTC
From: Ron Walters <rwalters@numail.org>
Message-ID: <486b84d6$0$80799$4c5efa9e@news.corp.moreusenet.net>
Source record: 24471

After reading several articles both on and off the WEB regarding a center fed antenna, only one article mentioned a recommended length for the feed line.

My shack is located on the second floor of a new home, (24') #8 ground wire to 8' ground stake with a further connection to the common ground point for the power and the rebar in the pored walls and flooring of the basement, telephone and cable. I plan on additional ground rods around the property and at a new tower. In a new home so progress is on-going.

The 1:1 current balum used to convert the 450 ohm balance line is external to the tuner, use about two feet of coax from the balum to the tuner.

Antenna is cut for 80 meters and using about 60-70 ft of line to center of the antenna. Where the antenna lines leave the shack is about four 4 ft from the location inside of the rig and floor mounted PC.

I use the antenna on all bands until such time I complete a new tower installation. I want to minimize stray RF around the shack since I rely on a PC and digital sound card as my primary source for ham enjoyment. I have already had some problems with a USB keyboard that I think may have been effected by RF when running over 50 watts on 20 meters only.

One article recommended odd multiples of a wave length is desirable at the lowest operating frequency while other articles don't address this.

I am having no problem with a match using the tuner on all bands 80-6 meters.

Have used the center fed antenna since 1976 but always had the shack on the ground level and had a good and effective ground system short runs with feed lines around the 90 to 100ft in length. never had a RF problem or surge problem.

Any recommended WEB sites or comments are welcomed.

For what it's worth...

I own an MFJ analyzer, not the RigExpert AA-200. Why? 'Cuz I can afford it, can't afford the RigExpert. While extreme accuracy would certainly be nice, I just don't have a need for that accuracy. If it get's into the ball park, that's usually close enough. The MFJ thingy is also a bit more convenient for me to use, no need for a computer, doesn't weigh a ton, and I can afford it. Is it the best? (Qualified) NO! But it works. Would I like to have that RigExpert AA-200? Sure! But not enough to buy one. Ahem... if someone should decide to give their's away.... some antennas, like the g5rv rely on a particular length of feedline because it becomes part of the antenna and radiates on certain bands. others use it as an impedance transformer.

> One article recommended odd multiples of a wave length is desirable at
> the lowest operating frequency while other articles don't address this.

that is a myth that has been around for many years. there is no 'magic length' that works better than others, except maybe the shortest length that reaches from the antenna to the transmitter. The only reasons to use longer lengths is if you need to use it as an impedance transformer because the antenna isn't matched to the line, or to allow for future rearrangement of the shack. what can be handy about the 1/2 wavelength line is if the antenna isn't matched to the line impedance the antenna impedance will be repeated every 1/2 wavelength along the line. so if you have a 300 ohm antenna and a 50 ohm coax, every 1/2 wavelength along the line you will see the 300 ohms again. this of course only works on harmonically related bands.

Cecil:

Say I had a situation where I must use a ground wire which IS an
appreciable percentage of a wavelength ... and don't wish it to radiate.

Could I accomplish this by using coax as the ground-wire and choking the
outer braid by sufficient windings on a toroid core, and grounding the
center conductor and the braid to earth though good and deep grounding
spikes or wires?

The only way to keep a wire--e.g., piece of coax--from being a
radiator is to keep net current at zero. If there's no net current,
you didn't need the wire anyway (at that frequency, at least). If
it's a protective ground for mains frequency, it will probably still
work for that purpose if you add ferrite for RF choking.

K7ITM:

I was hoping the rf/dc/ac could reach ground via a very low
resistance/impedance to rf on the inner surface of the braid and the
center conductor ...

While it would be virtually impossible to reduce rf on the outer braid
to absolute zero, I was hoping the choke would provide sufficient
impedance to rf to where it became near negligible, at least for
practical purposes.

```

It is also a myth that the feedline for the g5rv requires a particular length because it becomes part of the antenna and radiates on certain bands. At the antenna terminals the feedline becomes a transmission line with opposite directions of current on each conductor. Thus the fields developed around each conductor cancel resulting in no radiation from the feedline if it's dressed at 90° from the antenna.

```
In addition, it's also a myth that the feedline of a shortened antenna radiates.
Some believe that the portion of the feedline that makes up for the missing
length of the shortened antenna radiates--tain't so.

Walt, W2DU
```

Offhand, I would say you could accomplish a DC ground
that way but not an RF ground and not much lightning
protection.

I suspect you to be correct; a "free ride" is just too much to hope for
in these times.

Well, even a dc/60hz ground which does not radiate rf can be useful.

Fair enough, Doc. That's why I went for the MFJ in the first place.
It's not heavy, comes with its own carrying case with shoulder strap and its very portable.
I don't know where you get the need for a computer from.
You don't need a PC to use the AA-200. Its a added bonus if you want to connect it to a computer but you don't need to.
In fact, apart from testing the software and updating the firmware I haven't found the need to use the computer with it since. Not for what I need it for at the moment. This will probably change over time.
I get all the readings on the display of the AA-200 itself. So I get the best of both words.

If there's a net RF current, there's a net RF current, and it will radiate. It matters not a whit whether you say the net is on the inside or the outside or distributed between them in any proportion. If you choke things so there's no net current, you may as well not have bothered putting the wire/coax/whatever in to begin with. Consider what the current on the inside of the outer conductor must be if the coax is acting as a transmission line, and consider where that current goes at the "top" end of the piece you suggest.

To keep RF "out of the shack," put a Faraday cage around the shack and don't turn RF loose inside that cage. Then it doesn't matter (with respect to RF "in the shack") whether the Faraday cage is connected to "ground" or not.

What exactly is "ground," anyway? Do you think it has magical properties? What ARE its properties? What does it do for you?

64. anyone looking for truck tool box antenna mount?

Really, then I can throw away the current choke on my coax to my 1/2 wave vertical then? I THINK NOT!!! And, I DON'T think there is rf on the outside of the coax shield--I DO think there is on the inside of the braid ...

> ...
> What exactly is "ground," anyway? Do you think it has magical
> properties? What ARE its properties? What does it do for you?

Find an improperly grounded kw xmitter/liner whose case is hot with rf and running into a noticeable SWR, now touch a sharp corner of the case with your finger. Pay attention to the hissing noise(s), the flesh being vaporized into a white smoke, the characteristic white, deep penetrating, slow-to-heal rf burn(s) on your finger, etc.

Now ground the case and touch the sharp corner--notice the lack of pain?

Now, that you should get you started with what a ground is ... got anymore questions?

Now, I can explain all that without having to bring magic into the argument--but hell, go ahead, give me your "magical" version if you would like ...

I remember (some years ago) when I was a kid travelling a lot overseas with my parents, embassy rooftops and ships seemed to sprout HF Biconical antennas.

This was when satellites were not as widespread as they are now, and I guess most diplomatic (ciphered I guess) and maritime traffic passed over HF.

Why would this type of antenna have been preferred? Why don't amateurs use this type of antenna more? How do HF Biconnicals stack up against other HF antennas? Can they be trapped for mulitband use and/or loaded to reduce size?

I'd kind of like to home-brew a 20m one. Any ideas? Designs? Modelling software for them?

Tommie

Tommie,

Embassies needed to have reliable communication links. Most foreign embassies were equipped with transmitters capable of generating kilowatts of power if needed across the whole HF band. Efficiency wasn't a high priority, being able to send and receive messages reliably was all that mattered. Most of the routine daily traffic would have been encrypted teleprinter stuff sent via permanent scheduled radio links. In times of diplomatic tension, the regular frequencies might be jammed and hence the necessity to have equipment that was frequency agile and of sufficiently high power output to punch through deliberate interference.

Biconical antennas can be tuned across a wide range of frequencies and require less real estate than many other arrangements. Height is always good with antennas and the costs of providing lofty rooftop support structures and high powered transmitters with non interruptable power supplies are not really an issue for any diplomatic service.

Most of the old cargo ships used wire antennas running from the masts at either end of the ship. These were quite efficient and cheap. The disadvantage was that the rope halyards needed maintenance together with the hoisting blocks and wire antennas themselves. Funnel fumes wreak havok on phosphor bronze wires and insulators in a marine salt environment. Then the antennas needed to be lowered and stowed every time cargo was loaded or

discharged so that the cranes could work. The phosphor bronze wires would become work hardened through stretching and eventually break unexpectedly. I always had a complete new set of antennas with insulators and couplings made up in the radio room ready to replace any failures.

Oil tankers switched to whips fairly early on as the prospect of insulator arcing near to vapour venting from a fuel tank presented real hazards for the crews. Container ships also tend to rely on whip antennas because their stay in port is usually measured in the number of hours between successive high tides. There isn't time to keep raising and lowering antennas running the length of the ship.

The inefficiency of the whips is compensated for by increasing transmitter power. Not the most cost effective or ideal way for an amateur station to run.

As you can see, the requirements of commercial radio traffic are very different from those of amateur stations, although amateur stations may well use and adapt commercial techniques when necessary due to site restrictions or to provide reliable emergency communications for disaster relief, etc.

There is plenty of antenna modelling software that will allow you to explore their performance on the web, try EZNEC for a start.

Hope this helps.

Mike G0ULI

...which is balanced by the RF on the center conductor. If it doesn't radiate, there's no net current; the center conductor current is equal in magnitude and opposite in phase to the current on the adjacent inside of the outer conductor. Why would you think that what you quoted above would imply that you could get rid of the choke on your transmission line, if you want to keep the line from having a net current and therefore radiating? It says just the opposite. But of course, you already knew that, didn't you? Sorry, rhetorical question.

Interesting ... suggesting that if an inductance/capacitance it added
into the shield (or center conductor) and in series with such, so that
the current voltages between the center conductor and braid are 90
degrees lagging/leading that a net current would be possible between the
inside braid and the center conductor. But, still due to the choke on
the outer braid--impossible there (well, vastly reduced.)

Hmmm ... a name for it? Perhaps "Tuned Ground" or "Tunable Ground." <grin>

Actually, it took me awhile to put this together, your picture of "the ground" given in your text ...

Basically, we are two blind men, you have the trunk of the elephant in hand, me the foot ... but now that I think about it, I remember what picture the trunk brought to my mind ...

A radiating ground I have used before, my first exposure to one instance of it was like this:

In college, living in a couple of rooms rented to me by an individual having a home near the campus, I resided on the third floor of an old victorian (and, keep in mind, building codes were rather sparse back then.) The plumbing had been "reworked" and sections of it replaced with pvc. The old steam radiators had, had their piping removed in the basement level. In despiration, I had to resort to a wire ran around the base boards of the rooms and "adjusted" for various freqs/bands. This ground DID, indeed, radiate. Indeed, the "fuzz" on the video signal of the tv sets proved this absolutely--at times. The am band on a radio was also, frequently, troubled by my signals/rfi.

All the above, because the owner did not want "wires ran about."

The "ground wire" I was proposing would attempt to function as a transmission line, and simply carry the signals to a suitable ground; Whether you made that a legitimate number of buried radials of suitable length, a wire ran above ground and through the bushes, a wire connecting a few ground rods, or a run to the pipe in the basement, etc., would be at the users discretion ... however, the "ground wire" would be made to NOT radiate, or radiate as little as possible ... that is "the ground" (but actually, a "grounding transmission line") I was proposing with the coax.

Test Preparation Software

Pass your US FCC ham radio license test with ease. Our test preparation software
serves as a training aid to help amateurs and prospective amateurs pass the VEC's administered test. When you can consistently pass the test given by our test preparation software, you will almost certainly pass an actual test.

Our ham radio license test preparation software uses the latest officially released VEC's approved question pools. The program breaks the test into different sub-element. Integrated into the software are illustrations and Part 97 rules pertaining to the current question. The program tracks the progress of the tests taken. Once you have mastered each sub-element you are ready for the official test.

Visit our web site at http://www.hamradiolicense.net for more information.

75. Radiation and dummy loads

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-03 16:08:22 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <59ae9fd0-6cf5-46c4-8b7b-4757271fdec4@s50g2000hsb.googlegroups.com>
Source record: 24499

I am trying to understand why a low swr repetitive over a band of
frequencies is considered by hams to be a dummy load.! This
consistently shows up in statements by the itelligensia of this
newsgroup. Following up on the logic of that idea it would suggest
that if swr was totally constant (not sure how that could be) then
all radiation must be zero or self cancelling.?
This thus suggests that if a log periodic antenna was unlimitted in
the number of elements used would in the limit drop down to zero
radiation!. So following the thinking of this group the oscillations
that I show on my page

unwinantennas.com/

as a progression towards zero radiation since Q eventually is going to
equal zero.
Is this why the decreasing oscillation is defined as a dummy load on
this newsgroup?
The term comes up so often that I am compelled to look for what I am
missing, especially since carbon
is conductive and thus in the minds of many must therefore be
radiative!
Ofcourse the statement bandied around that if a material is
condunctive then it must radiatiate
could become fact instead of an old wives tales if stated enough
times.
Art

Has nothing to do with it. SWR and antenna efficiency are
not related. Also SWR and common mode currents, or
the lack of are not related.

>This
> consistently shows up in statements by the itelligensia of this

If Star Trek is to be believed, you are a carbon unit.
Tie a shielded feed line to your big toe and get back to
us on the amount of DX worked.
I'll even grant you the benefit of a doubt, and let you ground

your other toe to a suitable ground rod, radials, etc if needed
for proper operation of the carbon unit miracle whip.

> Ofcourse the statement bandied around that if a material is
> condunctive then it must radiatiate

I think it would hurt to see that statement repeated too many
times regardless if true or not.

The problem with your antenna will not be explained using fairy
tales and perceptions of what you think other hams might think.
All you need is regular old proven textbook theory which is available
to most anyone. If you have burned all your books in a past
fit of intellectual rage, maybe you should consider stocking up on
a few new ones. You can buy them online and have them delivered
via UPS, USPS, and other freight carriers. So you don't even have
to step outside the front door to gain this new perspective on the
"Unwin" antenna.

There is a webpage that calculates the correct length of the feedline
for an antenna:

http://www.qsl.net/w4sat/howlong.htm

> My shack is located on the second floor of a new home, (24') #8 ground
> wire to 8' ground stake with a further connection to the common ground

Since you are using ladder line, you don't really want a hwole lot of
extra length, since you'd have to figure out what to do with it. Ladder
line doesn't like being wound up - note this is what I've been told, I
never experimented myself. But it stands to reason.

> I am having no problem with a match using the tuner on all bands 80-6

The setup should work well. The grounding system isn't ideal, but we
work with what we have.

You did not present any logical thiknking on the subjet
Following the logic of my posting it shows a clear conflict between
normal thinking and mine. On on side we have the standard statement
that if it is conductive then it is radiative a pretty common
statement on this news group
Yet a dummy load is conductive ie carbon but is not considered
radiative, a clear conflict
My point of view which is objected to is that radiation is a measure
of the resistivity of the
current carrying material because that alone creates eddy current
depth sometimes refer to skin depth
dependent on the depth of current flow. Now eddy currents varies in
all current carrying members
where as carbon eddy production properties are minimal to zero even
tho it curries current, which is why it
it is chosen for a dummy load ie carbon does not produce a skin depth
of eddy current.
Thus the common thinking of a dummy load does not radiate or a current
carrying member always radiates
presents a problem In my thinking as neutrinos particle which is a
type of carbon because it is a side product of fusion
Thus by my definition a carbon byproduct will never rest on a carbon
product as a "free" electron

thus radiation cannot occur! The conclusion of the above logic is that a superconducting member
cannot radiate because resistivity is zero. On the other side of the coin copper has resistivity thus must be able to radiate
regardless of its resistivity contentand the swr figure represents the deviating frequency of the oscillating radiation which is in a direct opposition to the general thinking of today.Now your logic is a direct representation of the level of education you have attained
i.e.did not complete hight school. Since there are members who have exceeded this level on the group I assume there will be a
stepped ascention in the level of logic where both you and I will benefit.

John
I wanted a succession of logic starting from the bottom with respect
to education
and finishing on some hight lights and intuition with respect to
antennas and radiation
which is what this forum is for. You are entering much to early since
we all know that
the level of education and achievements with subsequent promotions
come with a rush
ONLY after a ham person retires from a mundane working life. You have
been to college and are still working
so there are many posters awaiting their rightfull positioin to post
and should not be pushed aside
at this early point.. Shame for shame hi hi Go back to the prior
posting to check and see whether the logic presented if any
is a close match to yours and then retreat until later. Note with
respect to logic I placed myself at the bottom to see if my logic will
survive by the time we get to the self perceived experts and who
amoungst them spoke out of turn!
Regards
Art

ah, so that is it. your logic is not normal thinking.

> In my thinking as neutrinos particle which is a
> type of carbon because it is a side product of fusion

is this an example of your abnormal thinking? seems pretty strange that a
small uncharged particle that passes through most matter as if it weren't
there could be a type of carbon which is an atom.

> Thus by my definition a carbon byproduct will never rest on a carbon
> product as a "free" electron

i just loaded up some graphite from a pencil (another form of carbon) and it
did indeed radiate.

> The conclusion of the above logic is that
> a superconducting member
> cannot radiate because resistivity is zero.

Whoa! then what about the guy that has patented a superconductive antenna??? you aren't going to tell me now that they issue patents for things that don't work????

Well, I will never accuse you two of not having a highly developed sense of humor! (and, that calculator is actually HIGHLY ACCURATE--error factor less than .00000000000000000000000001% <grin>)

At first I missed the importance of that URL, thanks for posting a reply to the original--I got a chance to use it. LOL!

Warm regards,
JS

The operative words being "normal thinking and mine (Art's)"

That about sums it up.

Well, yes and no ...

When you consider that the "normal IQ" is between 100-110 for the USA,
as a whole, and depending on the area in question (a survey onboard a
quality campus would blow that out of the water--and an IQ of 120+ used
to automatically qualify you for OTS (other qualifications
pending/applying) ... one could come up with a scenario(s) where
"normal" is not, necessarily, all that desirable ...

my formula is a little more complicated than the web site though. i take
the distance from the shack to the antenna, add in the width of the shack
(assuming some day i'll move the radio that it connects to somewhere else),
then add a couple feet more just for good measure.

Correct..... Normal in America is to strive to be a lemming
I can't be normal as it takes me more than one try to discern the
characters in the picture
which is needed before one can post

'
You know John, since America gives the 'right to bear arms' you would
think that the population would understand
that a projectile must have rotation to follow a straight line
trajectory.
Straight line trajectory is also a property of radiation, so we not
only have to eject particles at rest
from a radiator surface but we also have to apply 'twist' to the
ejected particle otherwise the particles will scatter!
Again the foucault or eddy currents come to the fore where their
```

circulatory action apply torgue to the ejected particle
Why is it so hard for Americans to understand that radiation is a result of radial ejection of particles via a rejective rotary magnetic field ?. Especially when particles in equilibrium is part and parcel of Gaussian law which when extended to the same environment as the Maxwellian law? Today we have total resistance to this evidence and instead prefer to act like lemmings rather than face change.
Regards
Art
I haven't purchased a ARRL publication for years but I suspect they are still talking of radiation as being wave form.

Art,
I think you had better stick to antennas, leave firearms alone,
don't go there. One of your earlier
statements covers all this very well. There's nothing wrong with
being normal, you know.

Hmmm ... I am still holding out a bit longer before calling the jury in ... the new developments of being able to take "pictures" of light waves/particles needs completely explored and given time for the technology to improve/mature.

But, it certainly looks the absolute proof of what light "is", is a LOT closer at hand. :-)

Regards,
JS

John , nothing wrong in having a weapon to protect your home and
rights.
It is when those same weapons are used to threaten and scare the
populace
that things go wrong especially when they suggests such threats to
repell free speech
and for all to read before hand! So a projectile must have rotation to
travel in a straight line
but you must not mention that as it is tyrinical. But he did come in

on time as I anticipated
and applied logic to antennas as he sees it. Soon others will take
their turn since logic
applied is getting closer to the norm
When the President was on a train aproaching my town a porter cried
out "ten minuits to Normal"
with respect to the upcoming rail road station
That is how the book by the presidents adviser from Texas was named
i.e. Ten minuits from Normal
so I am very familiar with Normal people
Regards
Art

OK, enough said; and this final comment of mine ends this "normal"
thread ... at least for myself.

You know as well as I, normal is much over-rated. Normal people are
just not that interesting. While violent nuts are a drag; and, nuts
which live in true "La La Land" cannot be tolerated for long periods of
time--the most interesting people lie in between these and "normal" ...

Well, that will sure cause heartburn for a lot of physicists, who believe it is a lepton, while carbon is an atom. Also the neutrino is massless as far as we know, and carbon very definitely has mass.

Now why do I think you will now tell me I, and the whole world of physics, is wrong?

Exactly. When they retired curiosity stayed with them and we learned
from their findings
There is little curiousity here which only gives people the past to
sieze upon with antenna bashing.
So they promote themselves as something they are not to prevent
learning from what I am sharing.
Nobody, but nobody has found fault with my findings because curiousity
left when they retired such
that they have nothing left to debate. Ofcourse that is not all bad,
no strain occures in bashing the messenger !.
I would be happy if somebody could find a fault in my findings to put
my mind at rest and I can move on
but trying to put fear in my mind by the bashing just plants my feet
more firmly in the ground
I find it so wiered that men of education denied the education
provided by the extension of Gauss when the mathematics are placed
before them to which they could find no fault. Probably because of
lack of knowledge in books behind which they could find safety.
We have a book writer here whose work was taken to task by another. If
he manages to get that same book published will you take shelter
behind what is written regardless of its quality? I find no shame in
what I am sharing and I will never be silenced so my feet turn to lead

in the face of wrong doing applied to others who have done no wrong.That is exactly how Hitler came to power where those who did nothing got their just deserts.

Make your point by proving it. Many will stand behind you
with that comment but first prove the mathematics presented are in
error.
That would certainly separate you from others who are not educated to
determine same
other than sharing with others what and who you are.
When those mathematics are proved to be in error my whole findings
fall apart .
. Where I would lose credence where you would gain without the need
for
insult which gains nothing. Is there not anybody in this world can
prove that the extended law of Gauss
when subject to the addition of radiators and a time varying field is
not the equal of Maxwells law?
Anybody from any country of any color or religeon willing to present
to Americans that indeed the
laws become the same? Or do you find the possibility of insults from
americans to daunting to speak up?
Be strong

You need to study your history.

Sounds like this to me:

First they came for the Communists,
and I didnï¿½t speak up,
because I wasnï¿½t a Communist.
Then they came for the Jews,
and I didnï¿½t speak up,
because I wasnï¿½t a Jew.
Then they came for the Catholics,
and I didnï¿½t speak up,
because I was a Protestant.
Then they came for me,
and by that time there was no one
left to speak up for me.

Gee, I have no idea why you say that.
I want somebody, probably from outside America who knows something about mathematics, communist, muslim or otherwise
who can inform the american ham where the similarity lies between Gauss and Maxwell . This is mainly an american forum
and they are determined to deny any mathematics that supplies a similarity between these two gentlemen from Europe. Mathematics shown up to now showed that Gaussian law of statics when extended to include a radiator and a time varying field cannot, and does not,equal Maxwell's law despite the mathematic manouvaring that show that they are the same. They also bring in to question antenna programs with optimizer that produce arrays where all is in equilibrium, or programs that show radiators tipped with respect to ground
as a response to Foucault current ala the weak field, required by the masters prior to Maxwell. We all know the statement regarding garbage in means garbage out and that is the label they are determined to foist upon all. The equality of these laws leads to the fact that a radiator may be of 'any shape, size or elevation as long as it is in equilibrium and is capable of producing eddy currents'.
This suggests to me that some members are full bent on preventing this knowledge being shared with all, for why I do not know
Even tho it was an american with a doctorate working for the space department who supplied confirming mathematics.
There is a need for efficient electrically full wave antennas contained within a smaller volume hitherto known and nobody can stop the advance of science where curiousity abounds. Somebody some where will produce one and then the race will be on but it disappoints me that it will not be America where the fall of the dollar will continue world wide.
Why american antenna engineers continue to pursue small efficient fractional antenna I do not know when the above presents the means of point radiation which leads to more efficient radiators of a smaller volume. I need a mathematician to come forward to blow this scheming apart for the benefit of all including those on the other side of the pond.
Happy fourth of July to all Americans and hopefully change is near.
Best regards

107. Question about Measuring and cutting coax length

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-04 10:52:36 UTC
From: Andy <dx90@blueyounder.co.uk>
Message-ID: <Shnbk.178582$NN3.81944@newsfe08.ams2>
Source record: 24531

I want to measure and cut some coax for 14.200 MHz. It is to be connected to my Cushcraft MA5B
I have cut off a 100 feet of RG-213 coax and have put a PL-259 on one end. I have a T connector connected to the analyse with a 50 Ohm dummy load on one side of the T and the 100 feet of coax on the other side of the T.
I then go into SWR mode on the Analyser and sweep, the nearest dip it gives is at 13.105 MHz. I expected it to be nearer to 14 MHz. Would this be about right?

Before I start cutting bits off the coax I wanted to make sure that this is correct or is there is a better way?

How crucial is the length of coax in the first place?

73 Andy

Since the MA5B instructions say that the feeder length is not important, why
do you need to cut the feeder to a particular length??

art never has understood that one of maxwell's 4 laws is really gauss' law
in disguise... sometimes written with a D instead of E to confuse the
clueless, its an important part of electrostatics.

Hi Andy

I think you'll will get into a large discussion over this!

I am no means an expert on this topic and everytime I need to be, I have to relearn a few things. In my experience though the almost only time I want to cut coax to length is if I am using it for Z transformation between antenna and TX. Like if the antenna has a Z of 100r I will end up using odd quarter wave multiples of 75r coax to "match" the system. I also use it to cut stubs for notch/band pass filtering and tuning . For one project I remember using a quarter wave length across the 5V terminals of an old SMPS to reduce radiation on about 75MHz.

What I am getting at is if the TX source Z is 50r and the antenna load Z is 50r any length of coax will do. The effect of tuning the coax length will be most evident if the system is reactive at either end. How much that difference it really makes I dont have experience in. I tend to shy away from coax systems in this case anyway as high VSWR on the line itself is a recipe for a large loss of system efficiency. (ie it has become part of the system tuning and can be regarded as a lossy load)

I normally use resonance/dip oscillator to determine length. If you only have a VSWR device you can figure the length by actually leaving the far end open or short and actually going for a maximum rather than dip.

I apologize for not giving you a definitive answer.

Cheers Bob VK2YQA

Hi Dave

One of the pitfalls is that although a VF of .66 (or .87 for foam) is
common it can vary considerably.

I dont think I have ever seen manufacturers VF specs with a tolerance
listed. In fact I dont think I have ever seen a manufacturers spec
include VF!

Of course it depends on how critical the application is. In my
experience for example 4:1 coaxial baluns on 2m always need to be tuned...

Cheers Bob VK2YQA

Of the two questions, how to do the 'finding the right length of feed line', and 'is it important', the last question sort of takes precedence. It just isn't that important at all.
The first question. It's been a while since I've looked at the instruction manual, but I think the analyzer's book should tell you how to go about it. (I'm too lazy to look, so take that for what it's worth.)

right, and for impedance transformers and stubs you have to take that into account and tune them individually. I do that for my stub filters here. But this is a case of how long to make it from the antenna to the radio from what little he told us, so vf is not important.

Yes, of course, (neglecting any loss in the cable).

>The effect of tuning the coax length
> will be most evident if the system is reactive at either end. How much
> that difference it really makes I dont have experience in.

It makes no difference to the vswr, all changing the cable length will do is
change its phase.
(again neglecting loss in the cable, and assuming that the cable impedance
matches the source).

Unfortunately, when SWR > 1:1, 50 ohms is at the
center of the SWR circle and is the target impedance
to which it is impossible to transform (unless feedline
losses are very high). :-)

But David you made a career of saying that you cannot add radiators
and a time varying field to
Gaussian law of statics.!
You are repeating the same method that Richard took by quietly
submitting to the fact that you were wrong during the last year and
now finally can see the light. Better late than never! Now you are
in position of that fact, get yourself an optimizer antenna program
and with one line where all dimensions are different i.e not planar.
Then come back and explain to the rest of America why the radiator is
tipped with respect to earth
(Tip review the combination of Foucault currents on diamagnetic
materials)

David I am so pleased that you have finally moved back into physics
Even learning to change the units of onbe law (SI) to the units of
another. Maybe other americans on the newsgroup will now follow you
without bashing other believers that it cannot be so.

Best regards
Art Unwin KB9MZ.....xg

"How crucial is the length of coax in the first place?"
As long as all the impedances are matched, and they are with RG-213 and a MA5B, length is irrelevant except that as-short-as-possible minimizes resistive losses.

73, H.

What? Are you telling us that you don't know math, and
request help to "inform" the American ham about Gauss
and Maxwell?

Let me get this right.. We all want to be clear on this.
You don't know or understand math very well, but you
want someone who does know math to "prove" a theory
cooked up by a person who doesn't use or know math
very well.
So, obviously if you don't know math very well, you must
not have used any to come to your conclusions.

What makes you so sure that the arrival of such a person
with credible math skills will verify and prove your
claims?
That doktor from MIT sure didn't do you any good.
I assume he at least knows a little math...

Sure seems like a stretch to me. We all know how you
came to your conclusions. And math didn't have anything
to do with it. Your antenna was spawned by twiddling
with an antenna modeling and optimization program.

I am sure that there are plenty here who do have the
math skills to calculate most any problem you were to

pose to them.

People can't check the math if no math is given for
them to check.
So what is your excuse for this gross omission?
And don't mention that doktor from MIT.
He didn't provide any math to check either.
What was his excuse for this gross omission?
Oh yea, I remember.. He ducked out and ran off
before giving his excuse.

Of course, you could greatly speed up your quest for
validation if you installed the antenna and ran tests
against known reference antennas.
You would know very quickly if your antenna lives
up to your hype or not.
You would not need any mathematicians to see
if your theory holds water. You would *KNOW*
without all the whiny histrionics.
Your pissing and moaning about peoples levels of
education strikes me as hilarious when you write
and spell on the level of the average 4th grader.

I don't know who your teachers were, but I feel
certain they must have been incompetent.
Either that, or in your advancing old fartism, you
have gradually lost most everything you were once
taught.
Either that or you just want to be different.
Which is it?

When are you going to get off your ass and actually
try one of these antennas in the real world?
If you won't do it, how can you expect anyone else
to want to mess with it?
The "normal" person will pretty much know it doesn't
work even before trying it. So there is not much
incentive to break a sweat is there?
If you want to prove that your air cooled dummy load
can be an effective radiator, it's all up to you.
Not us.
If you want me to break a sweat to disprove your
antenna, I expect to be well paid for my trouble.
You will also pay for expenses. IE: the hundreds of
feet of 22 gauge wire, two shoe boxes, etc..
If you wish, I will do your work for you for $6,150.00
$6k going to me, the $150 to cover parts and other
expenses.
You can send the check to my listed QRZ address.
After receiving said funds, I will provide detailed
test results within a week.

Note that I require payment before doing the test
just to ensure I actually get paid.
I'm fairly sure that the results of the test will be
unfavorable to your cause, which will likely lead
you to decide not to pay your bill.

Richard after all your denials regarding tipped antennas which you say
is a myth we are now getting close
to showing same via a computor program with optimizer which will show
it is not a myth. You will soon have to decide whether computor
programs with respect to antennas are complete garbage i.e. garbage in
garbage out or..... that antennas must be tipped for max vertical
gain. My guess that this will be shown first by a European since they
have a need for smaller antennas and still are willing to experiment
with antennas rather than declaring "all is known" Slowly the
correllation between static particles and Maxwell is being understood.
I never thought David would finally acknowledge the mathematics even
tho there are many who reject the fact. Now we have Richard ,not you,
David and myself on one side banded together against the antenna
bashers. The next move showing a tipped vertical generated by an
optimizer will bring another one over to my side. We then will see
that the static particles that is part of Gauss is ejected from a
radiator like an elevated frog, used for novelty reasons, show that
radiatiation is by particles and not a wave will bring another antenna
basher over to the Gaussian side. Then people will see how an eddy
current applies spin to a departing
particle such that it will attain a straight line trajectory for
communication and the change over will become a flood and you will be
left alone as an old man who cannot accept change While others are
making small antennas now that it can be seen that a radiator can be
any size shape or varied elevation as long as it is in equilibrium
This being the start of this journey connecting a gaussian field in
equilibrium to the mechanics of communication

Gauss' law is a statics law... always was and always will be. And i have pointed out to you repeatedly that it was already sufficiently integrated into maxwell's laws without you trying to muck around with them.

> Then come back and explain to the rest of America why the radiator is

its tipped because you are a bit off of vertical, and have been for a long time from the sounds of it.

> Maybe other americans on the newsgroup will now follow you
> without bashing other believers that it cannot be so.

i hope not, this is our independence day from the idiocy that you have been spewing.

what is the myth? they will do something different than a true vertical
antenna, but probably nothing really useful.

> that antennas must be tipped for max vertical
> gain.

if you want gain straight up then yes, you must tip the radiator, preferably
by 90 degrees off vertical.

> I never thought David would finally acknowledge the mathematics even

You haven't shown any mathematics to acknowledge... only bafflegab and hand
waving.

Buck
You are misunderstanding the situation with his antenna. What he is
doing is putting as much wire into the air which old timers still talk
about and then taking on the problem of feeding it. Since an antenna
can be any shape or size when in equilibrium he is following the first
part and getting around the need for equilibrium to get a smaller
antenna. This is somewhat like the Rhode Island antenna where winding
or distortion of a antenna was accepted first and the effort to place
it in equilibrium was taken on later .This was done by including the
transmission line in the antenna system which made a "smaller" antenna

David check it out to show the World why it is bafflegab,
The same thing was stated when the Gaussian/Maxwell
mathematics was given on this newsgroup. Be a hero and show the World
why America is correct and I am in error
Your chance to make the July 4 a day to remember for American hams
Ofcourse you can make an antenna where all lumped loads are cancelled
to form an antenna in equilibrium but that would mean getting up from
your
couch and putting your six pack down. Not very likely
Art

> why America is correct and I am in error

From "Fields And Waves In Communication Electronics" Ramo, Whinnery, and Van Duzer, 2nd printing 1967... ppg 237 they have just stated the 4 classical Maxwell's equations in integral form and are explaining them in words. equation (1) is the surface integral of the vector displacement = the volume integral of the charge density.... which they explain as "Equation (1) is seen to be the familiar form of Gauss's law utilized so much in Chapter 2. Now that we are concerned with fields which are a function of time, the interpretation is that the electric flux flowing out of any closed surface _at a given instant_ is equal to the charge enclosed by the surface _at that instant_" (emphasis shown by _ x_ is THEIRS not mine). Now note art, that this shows that the classical Gauss's law that you are trying to add into the Maxwell equations is indeed already there. Also, as they point out it implicitly accounts for time variation without the need to add a specific time term to the equations.

Wrong.
The chapter gives NO mention of the role of static particles in
radiation. Gauss never did apply an extension to his law of statics to
reveal that a radiator can be any size , shape or elevation as long as
the laws of equilibrium is in effect to make a dynamic field. This is
clear indication that a radiator must be of a wavelength or more that
is radiating which does not include the addition of a ground plane as
part of the radiator.
In addition, all laws only refer to distributed loads as a function
of radiation and equilibrium and where lumped loads have no part in
the equations. Equilibrium is also the datum proof where the charge
within a conductor must be zero so that the law of Newton can be
preserved (action and reaction)
By using the law of statics you find the importance of ":equilibrium"
that
Maxwell purloined as well as a new aproach to the sequences involved
in radiation
There is no question that the laws of Maxwell are not correct because
each law he purloined
included this stipulation as well as the extension to the gaussian law
of statics which
supplies the picture that Maxwell's laws are lacking. It is these same
particles alluded in Gaussian law
that are the true carriers of communication in radio where they are
ejected from the radiator surface with spin provided by the opresence
of eddy currents. Without the applied spin you cannot have a straight
line trajectory.
Ofcourse you can supply another reason why nature included particles
in communication which would really thrill me to bits.
But I am very pleased you are returning to written laws for proof even
tho you misinterprete them. On the other hand you can verify that the
requirement of equilibrium is preserved within Maxwells laws and thus
antenna computer programs such that the tilted vertical
is not removed from the subject of antennas. It was me that
speculated that these same particles were neutrinos that are radio
active and thus subject to decay that obtain a weak magnetic field
from entry to the earth's magnetic field which are present in the
billions per square metre on our native earth. It is also the
wavelength data that supplies the information regarding the parallel
tank circuit which is a pertinent part of all radiation. All these
items I have found to intersect like a jigsaw puzzle that adequately
describes the mechanics of radiation which hither to was unknown.
Unless ofcourse you have studies that are contrary to the above. If
you have, take them to the International conference on small antennas
organised in San Diego U.S.next week by the American IEEE where you
can drink in the applause of the World's experts

of course not, the aether was firmly debunked before they wrote that.

> Gauss never did apply an extension to his law of statics to
> reveal that a radiator can be any size , shape or elevation as long as

of course not, his law is a static law, it was maxwell that brought together
the 6 equations necessary to describe waves and dynamics.

bull. half wave radiators are just fine, and you can get any size conductor
to radiate.

rest of bull snipped... enough for today, i'm going to enjoy some nice old
scotch and enjoy the rest of the holiday.

Woww, you have slipped back into the abyss again. Statics and
radiation do not mix!
Have a happy Guy Faukes day with the fireworks

Methinks that may have already been the scotch ... ;-)

Anyway, my "1/2 wave" omini-vertical is a "full wave antenna!"

180 degrees of the rf wave, proper, is in the radiator--180 degrees is
in the counterpoise (mirrored, of course--or, 180 degrees out of phase
with the radiator (and, of course, is a radiator itself.) This is
mostly due to the current unun/choke at the base of the radiator, on the
coax. Else it does have a tendency to attempt to use the coax as a
counterpoise ...

Anyway ... yawn ... a full wave is being supported in the antenna
hardware proper.

Regards,
JS

A good way of looking at it for the layman since dividing a full wave
radiation by two you get close to the correct answer except for a
couple of ohms. But even that falls down with respect to a horizontal
dipole which is not in equilibrium and thus corrona can form at the
ends. With a quad antenna it then be comes in equilibrium where
Maxwells laws apply without chinanigans. Remember ground plains are
nothing but resisters carrying current and do not radiate because of
zero skin depth. The FCC covers this with broadcasters b y limiting
the level of ground plain resistance to I think about 2 ohms to cut
down non radiative losses.
All very fascinating stuff because the total circuit is then of a
parallel circuit nature with the inclusion of a dampening resister.
Cheers
Art

The preceding confusion not withstanding, surely you must have aligned
antenna elements to vertical or horizontal positions to maximize signal.
I`ve done so countless times while optimizing microwave paths.

Terman quantifies (look it up for the math, Art) signal degradation
caused by misalignment on page 923 of his 1955 opus. I`ll extract one
sentence:
"It will be observed that the quantity
(E cos psi cos theta) is the component of the field strength which has a
wavefront parallel to the antenna and is polarized in the same plane as
the antenna."

The programs Art refers to don`t contradict either Maxwell or Terman.

Best regards, Richard Harrison, KB5WZI

Not sure where you get the swr repetitive over a band of frequencies stuff, (perhaps I don't read enough of the group messages) but to reply relative to dummy loads in general....

Yep, Dummy Loads do radiate, they just don't radiate very well. In fact, most of them are encased in a metal enclosure of some sort to provide two major functions, reducing the radiation, and to provide oil or other medium for cooling.

On the other hand, your statement/question concerning whether anything that conducts also radiates, the answer is "yes" so long as it isn't shielded by something else, the skin effect helps provide that shielding (coax, with fields on the center conductor and the inside of the shield) or in a configuration that cancels the radiation with an equal and opposite radiation (twisted pairs, ladder line). Relative to carbon life forms, I've successfully loaded a tree and made (local) contacts, but the efficiency was probably near zero. Though many items may conduct and therefore radiate, their efficiency and effectivity as an antenna can be so low as to be readily compared to transmitting on a dummy load. Thus it is not unusual to hear ham conversations describing a given antenna/configuration as a dummy load...

> the antenna."

Yes they do!

Terman does not include the eddy currents vector where computer
programs based on Gauss and Maxwell and other masters do.
The angle of difference is similar to that seen as the pitch angle of
a helix antenna.
With your love of Terman you can now state that computor programs are
garbage
since they promote what you call a "myth"

>
> The programs Art refers to don`t contradict either Maxwell or Terman.
As I said earlier, yes they do with respect to Terman.
I challenge you to find in Terman the implications of Foucault current
with respect to antennas
and diamagnetic materials such as aluminum gold and copper which are
prime examples of material with suitable resistivity values
that provide ejection or levitation effects when moved thru a magnetic
field
It is nothing new, The vector has been there all the time it is just
that many don;'t mess with it because it is small and a devil to

calculate.
Richard why not give it up? You will never make the antenna, you can't operate computor programs and I suspect you cannot perform a google search, so progress beyond Terman is an impossibility for you. If eddy currents are omitted any structure thus made cannot be in equilibrium since this is the mystery "weak" force that Einstein struggled for in vain and thus drove him towards forming quantum mechanics., The masters made room for this force even tho they did not know what caused it but that vector was required to conform with equilibrium closed vector field

> that conducts also radiates, the answer is "yes" so long as it isn't

In a very general sense this is true because most if not all materials
at room temperature
have resistivity which is a measure of radiation. But there are some
materials that lose their resistivity
at extremely low temperatures of which the best known is a super
conductor

> shielded by something else, the skin effect helps provide that shielding
> (coax, with fields on the center conductor and the inside of the shield)
> or in a configuration that cancels the radiation with an equal and
> opposite radiation (twisted pairs, ladder line).

I have doubts about twisted pairs which is what I use for my
antennas.
The reason for crossed wires for me is to cancel lumped capacitances
and where the reversal of turns cancels imposed loaded inductances
Thus the length of wire used consists of only distributed loads as
required by Maxwells law
with length being N times wavelength. I have seen reference to
canceled radiation in some
antenna books but if I remember correctly the cancelling effect
occurs on near field radiation only.

Relative to carbon
> life forms, I've successfully loaded a tree and made (local) contacts,
> but the efficiency was probably near zero. Though many items may
> conduct and therefore radiate, their efficiency and effectivity as an

> a given antenna/configuration as a dummy load...

Interesting that you refer to life forms where carbon undergoes
various changes and classifications
as it decays, (c13) in the extreme. Tho I have seen some strata of
earth listed
as a carbon but then elsewhere as a mineral which I find confusing!
Ofcourse a tree consist of molecules
of water which is a diamagnetic material. Thus will have particals
drawn to rest upon it to radiate as well as particles
released by updrafts in a rainstorm allowing the particles to return
back to a suitable place in
quantum form as with lightning
Good posting

Gentlemen,
Well, I'm afraid it's time to reveal the truth to Art. Now that he's hit upon the tree thing, he honestly doesn't have far to go before discovering all of our secrets. While I admit that he hasn't yet touched on the mysteries of citric acid, he will shortly, I mean, it's only a very short jump, right?
Art,
You have been the focus of a conspiracy. Yes, your suspicions have been correct, it was a conspiracy by those of us 'in the know'. We have been doing all that we can to deter you from your venture into these mysteries. I'm sure you can see where the world is just not ready for them as yet. That was the reason, the world is just not ready for the revelation yet.
But it's time for this to end, the conspiracy thingy I mean.
Congratulations, I really didn't think you would make it, but you have.
I also believe you can understand that it takes time to turn this action of ours around and give you the deserved recognition you have earned. Be patient, it will happen shortly. In the mean time, you might give further thought on that citric acid (limes, lemons, etc.) thing and particle release. I knew you were 'close' when you mentioned trees!
Hang on, it's coming...
- 'Doc

139. PUFF 2.1

Does anybody have a manual for the microwave design package PUFF 2.1? Without the manual it is sort of hard to use. Also the source code would be nice. There is a package on the Internet that lets you recompile the code to run natively on Linux but does not include the source. I have the DOS version of the program now that runs in "dosbox" in Linux, but I would like to try the native version if I can. It seems that the California Institute of Technology isn't actively selling it any more. They direct people to try getting the German version etc or you have to buy some expensive book to get it.

http://www.its.caltech.edu/~mmic/puff.html

http://wwwhome.cs.utwente.nl/~ptdeboer/ham/puff.html (compile notes for Linux)

http://www.gerstlauer.de/puff/ (see bottom of page for zip file of executable file to download)

http://www.dosbox.com/information.php?page=0 (GPL licensed dosbox for various platforms)

Art -

The most important measure of an antenna is the amount of field intensity it can produce at a given distance in a given direction, per watt of applied r-f power. So far you have written nothing specific about this for the "Unwin" antenna.

Note that a transmission line feeding a 20 dB series attenuator attached to the input of a 100% efficient antenna will show very high return loss to the r-f source (> 40 dB plus the twice the cable loss). But that antenna system will radiate little of the available EM energy, nonetheless.

Could you please comment on the measured or at least the calculated RADIATION CHARACTERISTICS of your antenna, compared to a matched 1/2-wave dipole at that frequency (or an isotropic radiator), and tell us how you arrived at them?

If you can do that, and your results can be scientifically duplicated by others, you will have removed the source of a lot of the skepticism you read here and in your similar threads on eHam.net.

Otherwise it will be "more of the same," which (let us hope) is or should not be your goal.

RF

No.More of the same is not my goal nor is it to respond to every
request.
The mathematision or doctorrate type can do it solely by mathematics.
The computor program is built on those mathematics. and a antenna
program
will ALWAYs produce radiators in equilibrium which means at an angle.
Even without

a optimiser you can do it on Eznec but it would be laborious but it can be done.
People are enamoured with the Yagi so thay always insert planar type figures thus the
program which is designed around equilibrium. If the goal is small efficient radiators then
equilibrium must be present starting with a full wavelength that can then be placed in a small volume.
It is the smaller efficient radiators and arrays that I have pursued since radiation per unit length is solely a measure
that correlates with resistivity and it is that where my conclusions lie. Gain itself is a whole different matter
cannot show it's worth

Art:

1) I am not including your text.
2) You have struck upon an area I sift for clues.
3) Einstein did, indeed, realize that in those "weak forces",
undoubtedly, lies some important clues/finds.
4) Einstein even noted that the properties of the ether where/are
"unknowable", at least at the time he made such statement(s) and to this
present day.

Take an aluminum disk with a hole in the center to match an old wax
record and the hole the size of an old records. Tape a magnet to the
phonograph arm. Place the magnet/phonograph-arm on the aluminum disk and
spin it up to 78 rpm. The magnet floats ...

Magnetic fields/fluxes--electric-currents generated in the aluminum disk
are using "work energy" to float the magnet and maintain it at a
respectable height above the disk. This is not a "negligible"
phenomenon, it is used to levitate magnetic trains in Japan.

In our antennas, a certain amount of power IS doing a "like"
affect/effect. It IS wasting some amount of power in doing this ... it
is DOING "something" we are NOT taking into account.

Is this all related to the "weak forces" mentioned by Einstein? Probably.

Are these forces ignored in most if not all antenna calculations (or,
hidden in "magic numbers?") Yes.

Will new breakthroughs in antenna design result from the exploration of
these forces. I would guess that answer to be anywhere from maybe to
probably ...

And, there are even more of our "calculations" which ignore, or cloak in
magic numbers, such "abnormalities" ... like the old maps of ancient
mariners--these are areas, on these maps (antenna books, antenna
software, formulas, charts, etc.) with areas which are marked with a
peculiar notation, "In these areas lie monsters!" And they are shunned
and made "fun" of by most the members of this newsgroup; strange, if you
ask me ...

The future holds the truths (much like the X-Files! <grin>)

Well you are spot on in general terms but the numbers are there.
Farady, newton and others recognised that the Universe is within a
bounday
and from this vectors form. Each of the masters used this theorem ie
thrust and counter thrust
in ALL oif l their work So they would calculate all forces around a
point until a polygon of vectors were formed and where it was a closed
circuit which signified equilibrium.Now all the masters aproached the
laws of electromagnetism in the same way and each with the final check
with respect to equilibrium as the final check. All of the masters
aproached electromagnetics from different perspectives and there were
a lot of them. But every one of them came up with a polygon of vectors
that did not complete the circle tho all had the same missing vector
space. So they included this space us a vector the creation of which
was unknown but certainly present otherwise equilibrium would not
prevail. Foucault showed the rotative force, Corriolis, in his work
with the long pendulum which is why on my page I used a ploy from the
pendulum to dampen the response of the antenna vibrations. IN YOUR
CASE YOU ARE LOOKING FOR THE AETHER. But the eather can never be found
since boundaries within the universe exist with each other like a
bubble bath since our universe is just one bubble of many just like a
mass of frogs spawn.
Getting back to the weak force which is a vector of small length and
angle in the big picture of things such as with eddy current brakes as
you pointed out, but in the bigger scheme of things the same forces
act on earth as with a tornado where magnetic fields are huge
where elevation easily occurres within the vortex. In England after a
heavy storm it is not unusual to find vlumps of frogs that had fallen
from the sky because they consist of water a diamagnetic material,
that is drawn up into the sky and fall when their temperature falls to
a certain point. So with electromagnetism it can now be shown that the
weak force searched for by physicist is a direct result from a
magnetic fieldor force always makes a reactionary magnetic field or
force but the originating magnetic field quickly overwelms the
reactionary field (eddy current) which mask their presence.
However ,when the fields are time varying as with high frequency
within the tank circuit the time constant of the circuit makes them
more apparent and thus must be included in any laws revolving around
equilibrium.

The importance of this finding to me is that where the yagi is formed around collective coupling and recoupling to infinity,
radiators or arrays based on a border based on equilibrium achieves maximum radiation as a system where the coupling system
can never get to infinity. A small difference ofcource but one has finality where the other does not.
You may not follow my writing as it is always poor but hopefully you will see a small smigeon of scientific discovery in what I am presenting and how this weak force search by all finally comes into play because of the inter phase changes that occur in a tank circuit..Now I know it is impossible for some on this forum that cannot possibly follow the above b ut I do take delight when they do make a "authorative" posting as part of free speech which highlights the degree of expertise they reallyhave despite the self perceived qualities that they seek for to impress.By the way John I do have problems with the validation aspect of posting possibly because of spot eye problems. Does this affect you in any way?I can never get thru ia just one try
Best regards
Art

144. Why does the Lazy H antenna suck in the real world on 11 meters?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-05 16:42:20 UTC
From: Michael <spamtrap@shadowstorm.com>
Message-ID: <e4ae9836-71d2-4075-9823-fa1a11a90375@34g2000hsh.googlegroups.com>
Source record: 24368

I've seen the Lazy H mentioned in many antenna books over the years, so I decided to try one on 10 meters. According to the ARRL handbook the Lazy H is two collinear elements stacked on above the other, Each collinear element is made up of two 1/2 wave elements. I chose to use 5/8 wave spacing between the top and bottom elements. I connected the top and bottom elements with 450 ohm 16 gauge stranded ladder line (window line). After building the antenna I verified connectivity between the top and bottom right elements and the top and bottom left elements. I color coded the end insulators on each side so I could easily see which top and bottom elements were connected to each other. The antenna book says to connect the 450 ohm ladder line from the antenna tuner to the middle of the 450 ladder line that connects top and bottom elements. Ok done. Now I put up the antenna and make sure the top and bottom elements are in phase. That is both left connected elements are on the left and both right connected element are on the right. I also make sure there is no twist in the ladder line connecting the top and bottom elements. I also checked the other ends of the 450 ohm ladder line feeding the antenna has connectivity at the antenna, and the left and right sides of the ladder line do not have connectivity. The 450 ohm ladder line feeding the antenna is about 200 feet long.
Now I bring the 450 ohm feedline in to the house, hook it to my Dentron MT-2000 antenna tuner with the 4:1 balun inside, tune it up, and it sucks! Both my half wave horizontal dipole and my Solarcon Max-2000 blow it away on incoming skip even in the preferred direction of the lazy H. I rechecked my connections and the lengths of the elements and spacing and they are correct. I did take in to account the velocity factor of the 450 ladder line that connects the top elements to the bottom elements. The antenna book says the length of the 450 ladder lien between the antenna and the antenna tuner can e any lenght.
The bottom element is at least 1/2 wave of the ground, and the top element is 5/8ths wave above that. What did I do wrong?

Michael

in other words, he hasn't, he won't, and he doesn't care... therefore, more of the same handwaving and meaningless bafflegab. he doesn't have the math background to present his theory in any kind of a coherent form, nor of course could he ever measure his neutrino/carbon vortex crud because it doesn't exist, so he keeps going back to the same old crap... its not even funny any more, just sad.

If we are not equally open to all areas mentioned in your last post, I would at least grant you the right, interest, etc. in your explorations--there is "something" there alright ...

Your quoted text, above, I see different. The "universe" is like a hollow sphere. This spheres structure is penetrated by a LOT of holes. Just inside the spheres structure is a rubber bladder (balloon if you will.) This rubber bladder is under pressure, until it has expanded out though the holes in the spheres structure and formed spheres made from the material of the rubber bladder. In one of those lies our universe ...

Sorry I could not think of a better way to suggest this idea in time for this post ... previously I have only held it as a mental picture to myself ...

And, you are correct:

Aether = Eather = Ether

The first two I just consider "old world", and/or English spellings.
Since we Americans have "murdered" the Queens English, why not this word
also? <grin>

I'd have to look at a diagram of the lazy H, but I think that
is your problem. The elements need to be transposed.
Which means you want a 1/2 twist in the connecting
ladder line. IE: the bottom left should connect to the
top right, and visa versa.

David,
at this stage in life it would very difficult for me to go thru the
math from the start
in the exercise of adding a a radiator and a time varying field to a
Gaussian field
to show it is the same asMaxwell equation, very few of us are. But
when you come across a theorem
that makes sense to you it is gravy added when a mathematician comes
along to supply the mathematics
which you can follow in part. Then when antenna computor programs
supply the ingredients of such an analysis
which proves the same you have to get excited. When you then apply
what is revealed in such a trail and succeed in making a smaller
antenna that anybody has made you stop questioning what you have
found. As an aside, where do you view the atributes of an antenna with
near constant SWR reponse would find most use. I know most will jump

to dummy load but this I ask in serious form.

Art wrote:
"The computer program is built on those mathematics, and an antenna program will ALLWAYS produce radiators in equalibrium which means at an angle."

Arnold B. Bailey disagrees in "TV and Other Receiving Antennas". On page 367 he writes:
"The directional action of a rod antenna best can be analyzed by considering the rod as consisting of many tiny sections, connected together to form a metallic circuit. A typical small segment X - X is shown in Fig. 7-28 B; its position in a half-wave center-fed antenna is indicated in part (A) of the figure. Each tiny section may be taken sufficiently short compared to a wavelength so that the electromagnetic wave acts practically instantaneously throughout one section, and hence induces a substantially uniform current in that section. Such a short antenna segment has a simple directional response pattern, indicated in Fig. 7-28B, which is basic for all directivity calculations, since all antenns may be considered to be made up of these tiny segments. This fundamental response pattern varies as the cosine of the angle (which we shall call theta) between the direction of the incoming wave and the perpendicular through the center of the segment X - X, as indicated in part (B) of the figure. If E stands for the value of the field intensity (strength of the electric vector), then we can characterize the directional response by the relation Ecos theta, which gives us the relative magnitude of E for any wave direction relative to the antenna."

You probably have seen the figure-eight pattern of a dipole antenna and are already aware that maximum response is broadside to the antenna at its center. If the antenna is tilted away from the perpendicular its response is diminished. Other antennas have a similar response as all are made up of elemental segments.

Best regards, Richard Harrison, KB5WZI

As I understand it you only twist the interconnecting ladder line if you are feeding the Lazy H antenna at the bottom (end fire), but if you are feeding it in the middle of the interconnecting 450 ladder line then you leave out the twist. At least that's what I'm gathering from the pictures I have found.

One correction. I have a Dentron MT-3000a antenna tuners with a 4:1 balun and not the MT-2000.

I already gave you the quote that shows that Gauss's Law is part of Maxwell's equations already, you need no math for that. and since all the antenna design programs are based on Maxwell's equations they of course comply with Gauss's law... nothing exciting there.

the only use for a constant swr is to keep modern transceivers, that don't have a tuner, happy. swr has no correlation to performance of an antenna as far as gain or f/b or takeoff angle, things that are important to antenna design. i can take any antenna and give it a flat swr, there used to be a tuner on the market that did just that, until the league lab x-rayed it and found it was nothing but a dummy load potted in epoxy. the funny thing is, people liked it because it did exactly as it claimed, gave a perfect match across a wide frequency range... they didn't care that it turned a good percentage of their power into heat. so air cooled dummy loads as antennas can work, as long as you don't have anything better to compare it to... but I do, so I don't want one.

Richard, I understand where you are coming from since all these books
say the same thing. This says that the majority wins and thus is all
known. Well I disagree with that philosophy but I reckonise it. So I
am pushing my findings until I Art Unwin comes to rest with a
majoritory. Since I have an antenna that duplicates those facts I can
only hope that Industry sees something that they want since money in
this world is the driving force.
I am thinking of placing a sample of a tipped antenna on m y page b ut

I fear that all will then blaime the computor program and or Maxwells laws. You just can't make horses drink!
Art

David ,Gauss did a lot of work in his life time for which he is
recognised.
Are you saying that the "Gaussian law of static" was a prime mover of
Maxwells laws.
If this is so why does not Maxwells laws provide the role of particles
in radiation?
From my view point Gauss's contribution was supplied in other ways
that did not include the statics law but then I look forward to you
showing me where I am wrong

Hi Michael,

Normally spoken the feedline between top to bottom elements is
0.5lambda long, without twist, feeding in the middle. The path from
feedpoint to end of the radiation elements is 0.75 lambda, giving an
almost real low input impedance (on order of 30 Ohms, depending on
thickness of radiating elements). In fact you have two full wave
dipoles fed in phase that give most radiation (ground ignored)

perpendicular to the array (bidirectional). There is a vertical null

Why choosing 5/8 lambda vertical element spacing? You create a vertical lobe and a null in the elevation radiation pattern under about 53 degrees. You also get a strong reactive input impedance, but this may not be a problem with the ladder line.

Did you do some indicative field strength measurements (diode detector) to find out whether it (and the elements) do(es) radiate (comparing to the other antennas)? It may also reveal some hidden things.

Maybe somebody knows a loss figure for your ladder line (at 28 MHz) to assess the losses in the line (200ft part) because of bad VSWR.

Best regards,

Wim

> PA3DJSwww.tetech.nl
> When you remove abc, the mail does work.

Hi Wim,
According to the ARRL handbook the highest gain is achieve with a
5/8ths wave spacing between the upper and lower elements. The
handbook gives the following figures for estimated gain.

3/8 wave spacing = 4.4 dbd
1/2 wave spacing = 5.9 dbd
5/8 wave spacing = 6.7 dbd
3/4 wave spacing = 6.6 dbd

EZNEC shows a similar gain peak with a 5/8th wave spacing between the
top and bottom elements.

It seems to works on 14 MHz (stacked dipoles at 14 MHz), but on 10
meters the single 10 meter dipole blows it away.

O.K. you sound like you have the facts in front of you so I have no
alternative to do some research on the matter.
You could have saved me a lot of work if you pointed to a book or
something but I will dig anyway.
I will be gone for a while to see if I can find what you are looking
at. But then you have a reputation for lying
so you may have nothing but bluster!

The two laws of Gauss used in Maxwell are not laws with respect to particles.
I am now researching Heaviside to see if there is some derivitation there
But now I see you are playing games.It is just not true! I see that Feynman got the Nobel prize for describing the particals as Bosuns and "w:"which is a very long way from the gauusian trail of static particles!
So I will stop there as you are just playing games with the truth The bottom line is that the magnetic field created by Foucault current is the weak force in the Classic model and it was me that found it where Einstein and others failed. You just can't take that fact away from me. Really that is how it should have been with Maxwell and Heaviside and now me being born in the UK it is just a natural progression
Eat your heart out

Well I tried reducing the spacing between the top and bottom elements
to 1/2 wave spacing, but it still did not seem to make any
difference.

I've noticed in the past when working with ladder line that tuning an
antenna with an antenna tuner from about 14 MHz and down brings up the
receive verses by-passing the tuner completely, but that never seems

to happen once you reach 10 meters. I wonder if that has something to do with it.

I'm not sure, but if the Lazy H has Horizontal polarity and the folks you're trying to communicate with are using Verticals, there may be quite a bit of signal loss.
Since you mentioned it was for 11 meters, can we assume you're trying to communicate without using 'skip'?

It is meant for skip. I typed 10 meters at the start of the message,
but 11 meters in the Subject line. Old habits die hard as I started
on the CB band.

In my area, San Joaquin Valley, Ca--most 10m is on verticals ... while the guys running the "one size fits all" antennas--or, 80-10m (or, even 160-10m!) are mostly horiz--since a 10m is so easy, they slap up a 10m vertical also.

The "myth" that most noise is vertically polarized--well, I never subscribed to that (but, when I was a kid, I first believed it!) Most runs off above ground power-lines are even, somewhere, around a 45 degree angle (and, above ground power-lines are ALWAYS horiz polarized! Drive around and look, maybe they do it different in your area ... ???

And, now, most power-lines have went under-ground in my area ... vertical is fine with me and I don't send my signal skyward or into the ground, where it may reflect into the stratosphere anyway ...

Regards,
JS

Quoting the ARRL Antenna Book: "It should be designed
for the higher of the two frequencies using 3/4 lamda
spacing between parallel elements. It will then operate
on the lower frequency ... with 3/8 lamda spacing.

If you have 5/8 lamda spacing on 20m, you will have
5/4 lamda spacing on 10m with poor performance.

Not only that, but will depend if feeding end fire, or broadside.
It's only as a broadside array that max gain is at 5/8 wl
spacing.
And he is feeding his as an end fire array. The elements would
need to be end to end IE: collinear, array to be fed as a broadside
array.
As an end fire, the spacing must be quite a bit closer. If I remember
right, max gain with an end fire array is appx 1/8 wl spacing.
But from my own experimenting around with them, it's not
ultra critical as far as getting them to work.
In my case, I was feeding each element with a separate
feed line, and changing lengths to steer the array.
It was quite crude, but worked pretty well.
In my case, I tried to compromise on the spacing so I
could feed it both end fire, and broadside. I think I used
about 1/4 wl.
I also used about the same scheme on 10m, using two
5/8 wl ground planes. I forgot the exact spacing I used.
It was more dictated by available mast/.vent pipe locations
more than trying to get an exact length.

But it was a compromise spacing, and I fed it both ways
depending on the pattern I wanted.

Just thinking about another thing.. I think feeding in phase
would give a bi directional pattern, but if he wanted an
omni directional pattern, I think he'd have to have the elements
90 degrees out of phase. But I fergot...
He could fire up eznec demo or whatever and he can
quickly get a pretty good idea what to expect in theory
with any particular spacing and phasing.
He could crudely steer the pattern if he used various
length feeders to each element.
Some also use the "L/C" phasing boxes to steer the
pattern. Again fairly crude compared to some methods,
but it will work. Just don't expect perfect textbook patterns.
You have to take what you get...
The ARRL antenna book has better methods if want
cleaner patterns.

Or, if you don't wish the built-in limitations of Eznec (the demo
version), try MMANA GAL. Will feed the same data to the nec engine(s.)

Ya know what, I guess he is running as a broadside
array after all.. I was thinking he had the elements
horizontal, but after rereading the first post, he does
have them stacked.
And if they were in phase, that should be a broadside
array.
Sooo... I finally decided to check it in the program using
two 1/2 wave elements for 10m, with the lower element
at 1/2 wave up, "16 ft", and the upper one at appx 5/8 wave
higher. "37 ft"
Using the single lower element alone, I got 2.08 dbi.
Using both in phase, I got 6.8 dbi.. So, it should work
as planned.. Not sure what the problem would be though,
unless you have coupling problems with other metal in
the area, etc..

Hello Michael,

You mentioned that even your hor. dipole blows away the Lazy H (also for good orientation). This rules out every influence because of minimum elevation angle of main beam versus ground conductivity/ permittivity.

I assume that you are talking about several S-points. There must be something really wrong. The dipole close to ground will have some different impedance (then the upper). This will cause some phase error, but this should not lead to a drastic reduction of overall gain.

According to your postings, the construction is OK (no twist, feeding in the middle). I also assume that you have some spacing between the 5/8 lambda long vertical line and the actual feed line (of 200ft), to avoid coupling between the two.

It can be the line, or the tuner/balun. Line Losses increase and when your VSWR in the line is very high, this may increase the overall loss in your 450 Ohm feed line. If possible compare the field strength of your hor. dipole with field strength of the lazy H.

Other option is to find an unused frequency en put in lots of power and look for temperature increase.

Best regards,

Wim

" But now I see you are playing games.It is just not true! I see that Feynman got the Nobel prize for describing the particals as Bosuns and "w:"which is a very long way from the gauusian trail of static particles! So I will stop there as you are just playing games with the truth The bottom line is that the magnetic field created by Foucault current is the weak force in the Classic model and it was me that found it where Einstein and others failed. You just can't take that fact away from me. Really that is how it should have been with Maxwell and Heaviside and now me being born in the UK it is just a natural progression
Eat your heart out
Art Unwin KB9MZ
unwinantennas.com/"

Art,
You may be fond of the idea that you are being persecuted because of your being English, or from the UK, how ever you want to put it. If so, then I'm sorry to disappoint you, but your birth place has very little to do with how, I would suspect, most people think of you. (I'm also sure that part of the 'problem' has to do with translating between "King's/Queen's" English and what is spoken in the USA. Sorry 'bout that, but that's normal for any two languages. It works in the other direction too, so you are not alone.)
You are your own worst enemy as far as being taken seriously. You probably have no difficulty in 'following' your train of reasoning, but us 'lesser' people do have that problem. How about helping us with that problem? I have a suspicion that it will take a lot of time and work on your part (as in book sized volume?). But, unless you want it to take 'for ever' for you to be understood, it's going to take that effort. If we can't follow your train of logic, you're just not gonna sell many tickets to ride that train.
So, it's up to you.
- 'Doc

(I came to the realization that I wasn't ever going to be in the same 'class' as Einstein, Maxwell, and Heaviside a long time ago. And quite frankly, it doesn't bother me. Sort of like winning the lottery, first I have to buy a ticket, and I'm too cheap. What abilities I have just don't 'lean' in that direction.)

Has anyone here actually built a Lazy H for 10 meters that worked?
In my previous post there was alot of references to published material on the Internet as well as alot of people using computer modeling software to check out the antenna. I've already done all that, but when I actually tried to build the antenna on 10 meters it did not work. It's performance was awful. When I try to tune it up on the antenna tuner (Dentron MT-3000a) the antenna adjustment on my tuner is almost all the way over to the right, and the transmitter adjustment was tweaked a little over to the right as well. I decided to try a different antenna tuner, so I hooked up my Drake MN-75 antenna tuner with the 4:1 balun installed and was once again I had to just about max out one of the variable capacitors to bring the SWR down. Once the SWR was down the receive was still way behind the Solarcon Max-2000 and the 10 meter horizontal dipole.
Has anyone actually built one of these and made it work well on 10 meters? If so how did you feed it/match it?

Michael

I found an article that shows using a 1/4 wave matching stub at the
bottom of an end fire Lazy H with 1/2 wave spacing. Perhaps even
ladder line transmission line needs a matching stub.

Looks like another user had similar problems with a Lazy H using 450
ladder line all the way to the tuner. Like me his will tune on 14 MHz
where it is basically stacked dipoles, but once you get to 10 meters
it is a no go. He tried 450 ohm ladder line to a balun as well.

It could be said also that it is good enough for practical design of
near perfect antennas. All of Art's voo-doo theory cannot hold even a
candle to either concept!

particles are not necessary, so of course not.

> I keep on reading that radiation is not fully understood

which books? quotes please, not hand waving. i have given you quotes, now
you provide the ones that your theory is based on.

> Give me a book that does understand and provide
> the role of particles and then make us all happy

go back to one of the aetherist's and you can have all the particles
propagating waves that you want... but they still won't work like your
neutrino/carbon things hopping off diamagnetic materials.

Arthur doesn't provide specifics. He doesn't provide the math. He is short on fact and long on misspelled pontification. Excuse me if I don't accept his wild claims at face value. If he can't explain them (and the burden of proof is on him), why should any of us be bothered?

Hello Michael,

The concept can work at any radio frequency. I didn't build them on 10m, but I did on 433 MHz, 868MHz and 2450 MHz (over a reflecting plane to get unidirectional pattern), both with 0.5lambda spacing and more (to get more gain, and some side lobes).

There is one difference with respect to your setup. I designed for 50 Ohm input impedance in the middle so that I have no high VSWR on the feed cable. Depending on the thickness of the radiating elements you may have a VSWR of about 15 on your 450 Ohms feed line.

When the distance from end of radiator to feedpoint is about 0.5lambda, the impedance is real and low (about 30 Ohms, depending in thickness of radiators). This interfaces good with a 50 Ohm coax. 2 years ago a planned to build one for NVIS operation at 80m (pastoral wet soil as reflector). I didn't build it as the HW dipole with 3 reflecting wires did perform more then well.

I concluded from your posting that you simulate also. I think your problem is in the matching and tuning. So try to lower the VSWR in the feed line and or examine your tuner.

Best regards,

Wim

Source record: 24420

There are lots of particles called Neutrinos that wander from the sun
to earth and else where in the Universe.
Scientists say there are billions of them per square metre on earth.
So what are these neutrinos?
They come from the Sun as partialy decayed nuclear particles like
that comes from a fire
only the fire in the Sun is a nuclear reaction and tho there is heat
generated the particles driven off
still have a half life or so of nuclear constituents so they haven't
fully decayed and have miniscule energy.
The Sun is in its own arbitary boundary or gravity field,where all
forces on the outside of the boundary equals the forces inside the
boundary such that the boundary contents are in equilibrium or
balanced.
The Sun has a :"pole" just like earth does but the pole revolves more
than the one on earth, 22 years for a full turn where the earth's pole
turns in terms of once in thousand of years. When the pole turns
within the Sun it puts a strain on its encircling arbitary border such
that the Neutrinos escape in volume until the forces rearrange in
equilibrium, or at least tries to. But the release of particles pretty
much escape all the time untill it reaches a maximum where the pole
has aligned to 180 degrees from where it started. Escaping particles
start then to taper off until the poile gets back to its starting
point 22 years later when it starts its rotation again
Now neutrinos are extremely small and when the escape they lack
direction because the particles have very little spin to them so they
drift in all directions. Now these particles are electrons of little
energy and thus they have to be carefull where they settle otherwise
they will be absorbed by the matter and take up a contained spin
within the particular mass. Fortunately the majority of elements on
earth will allow these particles to rest upon them without
interference but first the neutrons have to enter the earths
atmosphere and tho they have little energy they do become magnetized
by earths polar system before they get to a resting point which is
often a antenna element made of a diamagnetic material such as copper,
gold aluminum etc. Diamagnetic materials are those that have excellent
conductivity without hystereses being formed where energy is being
wasted ., In fact the conductivity is so good that the magnetic field
formed
produces another magnetic field in opposition to the primary field and
this counter magnetic field becomes very apparent when the electrical
and magnetic field exchanges are very fast from a circuit in "tank"
form which is the equivalent electrical circuit of a full wave length

antenna.
So to sum up,
We have a diamagnetic antenna wavelength where the material is of aluminium and where its surface is fully covered with decaying nuclear particles that came from the Sun with very little energy, extremely small and enclosed in a permanent magnetic field that it gained while entering the Earth's system While all around the radiator in the atmosphere there are billions of particles looking for a resting place and the competition is fierce

The next posting will explain the magnetic fields that are formed when a time varing current is applied to the radiator which is in the form of a "tank"circuit which is the electrical equivalent. I will answer questions related to the above as long as they are sensible and obviously in search of clarity

I'm starting to think Art has been fooling us all along.
This surely must be an effort at usenet deep sea fishing.
I think he's fixing to reel us in with these tales of happy neutrinos.
I guess about the only coherent question I could pose to such
an "Article", would be to ask what in the heck do neutrinos, fig or
otherwise, have to do with the radiation characteristics of an
antenna?
Besides, the sun is not supplying the RF to be radiated. We are.
My cat needs new mittens. It seems to old ones were consumed
by a bombardment of neutrinos looking for a resting place, and
the motel was full up for the night.
They went postal, and a rubber room is in their future now.

I understand that your education is limited but in your short time at
high school
before you were expelled as you say that most students paid attention
to the lesson at hand
and took notes because another day education will continue and where
you cannot possibly get every thing done in one day.
If there was any part the student did not understand then it is up to
him to do a little bit of research that will broarden the scope of
notes taken. If a student does not do this then he will rapidly fall
behind as the blanks pile up on their education Now you are at a point
where you realize you already have a lot of blanks so you want to stop
the teacher doing his job by teaching the class as a whole by
demanding personal attention because you were not playing attention or
taking notes which in effect is robbing the other students time and
education. Thus when exams come along you fail and are asked to leave
for the benefit of the remaining students. Ofcourse you can vent off
your feelings to the teacher but the fact is you cannot go back in
time without loss.
```

So ! Before you read the following posts regardless whether you dislike the format you have an opportunity to bone up on what I have written and fill in the blanks left of your notes. When the next writing comes along you will be comfortable knowing that you are prepared to continue with the other students from where you all left off as an equal !. Sounding off does nothing for you, Go to the library and do some research so you can catch up or stay with the other students without any blanks in your notes otherwise you are on a one way street towards the exit with opportunities lost. Do you really want to go back to your high school days and be asked to leave again? Being a comedian will not help you in the final analysis as others will view you with sadness. So pull yourself together and get to work so you will be equal to others when the next challenge comes along.

You can't answer a single question posed to you.
All you offer is whiny excuses.
Your constant whining about my education strikes
me as hilarious being as your mechanical engineering field
had little to do with antennas. You don't seem to have any
special mathematics skills that I can notice.
As far as I can tell, you have no real academic advantage
over me whatsoever when pertaining to RF or antenna
systems.
Or if you do, you have obviously forgot it all.
But proceed o' masterful one of the land of air cooled
resistive loads. Enlighten us mere peons of the antenna world
more of the gospel according to Art.
It's not every day we get to ponder the universe with someone
who thinks they are a "master".
You are better than the sci-fi and comedy channel put together.
Proceed o' illustrious one!
With acid reflux breath I await.

Keith, congrats on your upgrade!!

The old saying is, any antenna is better that no antenna, so to get going why not build a quick starter-upper that will work on most all the bands. While many might call the "G5RV Dipole" as a poor antenna, it actually works quite well and is easy to make. There are a number of sites on the Internet to guide you, but all that is necessary is 102' end to end dipole fed with 31 feet of balanced line in the center. If you can tune it at that point great, but you can also add 50 coax at the end of the 31 feet into the shack. Make sure you get it up in the air as high as you can and keep it a flat top installation if at all possible. It will also work with drooping ends too, but keep the end high.

On 20 Meters the antenna is a 3/2 wave dipole, and it has gain of 3db and radiates off the end of the wires. Due to the present conditions of the solar cycle, try to install it in a direction that would work well 20 as it will be your first band to work "long haul" contacts. You will find 40 and 80 to work too.

BEST REGARDS,
Steve K2CX

202. Seeking New FAQ/Intro Maintainers for rec.radio.amateur.*

I suspect with your long feedline length (200 ft you said?), and the
probably very high SWR on the feedline, you have significant feedline loss.

Also, are the elements really horizontal? Or are they closer to inverted V's?

On posting part one I finished up with a reference to a full
wavelength antenna and we need to talk about this choice of a
wavelengrh. Equilibrium comes from Newtons laws where force equals
reaction force or upthrust equals down thrust where all forces around
a point equals zero. All the masters such as Faraday,Gauss and others
based all their discoveries around this notion.. In the last century a
frenchman saw this as a period in a occillation of a repetitive nature
as being the point where a cycle of events begin again. In other words
a full cycle was completed and another cycle started. This Frenchman
by the name of Foucault built a large, long pendulum in terms of a
hundred feet to deetermine the time of one sequence of events that
signifies equilibrium.
To his surprise the pendulum not only swung left to right and back it
also moved rotaed about the center a slight degree. This meant that
there was another force, a rotational force must be at work over and
above the two dimensional swing and thus for true equilibrium a period
is many times a single to and fro movement.
Thisw is analagous to our year system of time where every four years
we add a correction to the period of time
by summing all these slight incorrection of time as a full day in what
we term as a leap year.
This is the reason for the choice of a full wavelength radiatorl since
it represents a single oscillation of its harmonics PLUS this small
extra force required to meet equilibrium. Stated another way, this is
the force that is missing when the amplitude of a oscillation does not
quite reach the amplitude of the previous oscillation.
Foucault also went on and discovered "eddy current" which is a
reactionary current to any initial current as
predicted by Newton This is a very important factor in the design of
transformers i.e. laminar flow. What Foucault found that the initial
time varying current in a conducting member produces a magnetic field
and then produced a counter current that produced another magnetic
field in opposition to the intiating field!
This opposing field was very smal in energy content and normally is of
no consequence in our dealing with electro magnetics since it is
easily swamped by the initial magnetic field. But Foucault found that
if the conductor was a diamagnetic material with high conductivity its
effect became more visiable when the current was alternating at a high
frequency and it came to be that this counter field represented the
same energy that was lost from one occilation to another of a
radiator .This force some times called the WEAK force must be added or
included in any oscillation such that equilibrium is achieved. Thus
equilibrium is an important factor in our universe and like leap year
we have to add this force whether it is frictional or otherwise to

acceed to Newtons law. and since a wavelength equals on period or oscillation I also must retain this force for balance or equilibrium reasons
I will stop at this point so one can really get to grips on the term equilibrium or balance which if not present
would hurl our Universe to places unknown because of its loss of stablisation The above is extremely important with respect to radiation because this same secondary current that supplies a secondary field is in direct opposition to the Neutrinos field sitting on the same conductor with a very small magnetic field of an opposite nature and where the battle begins with respect to radiation.
Please. please get a full understanding of the meaning of equilibrium before we get to the next part
Note Most books on this subject ignore this very tiny force as immaterial with respect to the scale of other forces involved
This allows them to basically deduce that an effecient radiator must be at right angles to the earths surface IF and only IF this small force known as the weak force is ommitted from their calculations.
If it is included to meet the laws of Newton and to be in equilibrium the weak force shows its presence by tilting the radiator relative to Earth.(More on this later)

Hi Art,

The American Constitution does not "give" rights. It simply attempts
to prevent government from eliminating them.

Under the influence of gravity, sub-orbital ballistic projectiles
generally follow a parabolic trajectory. Isssac Newton's laws of
motion apply without caveat.

No constitution or law can EVER give rights ...

You are born with all the rights possible. Unless you are under a constitution or law(s) which remove some (or all) of your rights--you have every damn one of them! And unless there is a clear majority of a govt's citizens which support that constitution/laws, you are witness to an unjust constitution/law(s) ...

As our constitution notes, these are God given rights--no man may ever take them away--you CAN agree to a contract NOT to exercise some of your rights to the betterment of all.

Men get together and form govt's and agree to create laws which limit their rights--FOR THE GOOD OF ALL. When that no longer is happening, it is time to reform, re-elect or even go as far as a revolution to restore just rights ... our constitution makes that a duty for Americans, and requires us to remain ever vigilant in the protection of our rights.

If you believe laws give or protect your rights--you already have lost them to a guy on the street playing craps ...

SGC is probably the best-known brand of these tuners (although I understand that they did not create the basic design). If you go to http://www.sgcworld.com/PubInfoPage.html you can download the SGC-237 manual, which has a complete schematic.

The impedance-matching network in these tuners is a pi network, with two switchable sets of capacitors making up the input and output shunt legs, and a set of switchable inductors making the series (top) leg of the pi. The capacitive and inductive legs are each composed of a group of components whose values are generally in something akin to a power-of-two relationship (e.g. 25, 50, 100, 200 pF), with individual relays to connect or disconnect each individual component. The relays are controlled by a microprocessor. By switching in/out the individual components, the microcontroller can set each of the three legs of the pi network to a reactance which can be varied over a fairly wide range.

The incoming RF signal from the radio goes through current / voltage / phase detector circuits that then feed into the microcontroller.

During a tuning operation, the microcontroller can use the voltage/current relationship, and the signal phase, to determine whether the (transformed) feedpoint impedance is above or below 50 ohms, and whether its residual reactance is inductive or capacitive. The microcontroller then adjusts one or more of the three legs of the matching network, re-measures, and tries again.

This sort of tuner seems to have several quirks or limitations. Programming the search algorithm to find the right match (or *a* correct match - often, many are possible) apparently isn't easy. The SGC tuner I have seems to be easily "confused" if the radio varies its power during the tuning process (e.g. as part of a high-SWR power foldback).

Frankly, I wouldn't recommend a project like this as a one-off hobbyist project, even for a real enthusiast. I can see it becoming an incredible time-and-effort-sink.

A somewhat similar tuner, which would be much easier to build, would be one which implements a "pi" or "T" tuning network using motor-driven air-variable capacitors and a relay-switched multi-tap inductor (or perhaps a motor-driven roller inductor). You wouldn't get the very rapid bandswitching of an automated ATU, but would

probably have lower losses, much less physical complexity, and a
better chance of getting (and keeping) it working.

A "tuner plus whip" setup for a vehicle is often very electrically
inefficient, at least on the lower-frequency HF bands - you can end up
with most of your transmitter power being lost as heat in the tuner,
due to the very high circulating currents flowing between the pi-match
inductance and the very-capacitive impedance of the whip. My
understanding is that a whip/tuner setup is often a couple of
S-units poorer than a decent screwdriver antenna, and even worse than
that compared to a well-designed-and-built single-band "bugcatcher".

On the "plus" side, though, you do get a lot of physical ruggedness,
since the whip itself is sturdy and easily replaceable if it has a
serious disagreement with a tree branch.

There's also the original LDG design, which was featured in a QST article.

> The impedance-matching network in these tuners is a pi network, with

or as an L network with series L and shunt C, which is switched to
either input or output end. (that's what the LDG tuners do)

> This sort of tuner seems to have several quirks or limitations.

This is the heart of the tuner and whether it's "good".. what's the
tuning algorithm.. The mechanics of switchable Ls and Cs (or motor
driven Ls and Cs for that matter.. another QST or QEX article had one of
these) is fairly straightforward, it's the fast tuning.

>
> Frankly, I wouldn't recommend a project like this as a one-off

Especially since you can buy the already built unit for less than it
would cost to buy the parts to build it...

>

The losses might be about the same. (For example, the SGC tuners use
air core inductors.. same as you'd have with your multitap inductor..
and getting suitably high Q ceramic caps is pretty easy)

>
> A "tuner plus whip" setup for a vehicle is often very electrically

Well... as long as the wire from tuner to whip isn't something like coax
with the shield grounded, the efficiency isn't all that bad. Of course,
it's possible to configure the tuner for a "bad" configuration (as you
mentioned, there's multiple "solutions" that generate a match, some are
better than others, and that's where the cleverness in the tuning
algorithm comes in)

My
> understanding is that a whip/tuner setup is often a couple of
> S-units poorer than a decent screwdriver antenna, and even worse than
> that compared to a well-designed-and-built single-band "bugcatcher".

I don't think so...

2 S units is about 12 dB..

If that were the case, the tuner would be dissipating more than 90-95%
of the Tx power, and it would melt.

There's a fair number of measurements out there on tuner losses, etc.,
and none of them are credibly at the 90% level... maybe a couple dB,
except in a pathological case.

Your big hit is just from having a short antenna and a crummy ground (in
the vehicle case).. Easily a 6-12dB hit over a dipole over the same
ground, but there's nothing you can do about it, because, especially on
lower bands, you can't drive around with a 60 foot dipole 30 feet up.

The single band bugcatcher has higher efficiency AT A FEW FREQUENCIES
and is appalling once you get very far away, which means it's not really
an apples to apples comparison with a frequency agile system. If you
operate on a few select frequencies (e.g. you have a 40m or 75m net that
you participate in on a regular basis), then the bugcatcher approach is
more attractive (but I might still contemplate using a tuner.. just put
it in bypass mode when you're "in-band")... and the bugcatcher is still
going to be down 6dB from the dipole.

213. Part three of many

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-08 03:38:58 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <27717f6c-c5fe-4ec6-849a-4ec7498fb6bd@k30g2000hse.googlegroups.com>
Source record: 24437

Part two I finished up talking about eddy currents that form a
magnetic field in opposition
to the primrary magnetic field. It is this eddy current that is
considered a loss in the building of transformers
and forms as a circulating current which can penetrate quite deeply in
a transformer. To cut down this loss a transformer is made of
laminated steel parts bound together so the depth of the eddy current
is confined to a single laminate to control its penetration or skin
depth. Eddy currents formed on an antenna are also circulartory such
that the current flow is at right angles to the applied current flow.
So the conception of skin depth of a radiator as being some sort of
high resistance or corrosion skin is not quite correct. What we
actually have is a force or current running into the side of another
current flow so that the summation of such is deflected sideways and
upwards in three dimensional terms.
As I mentioned earlier this eddy field or magnetic field comes into
contact with the magnetic field of the particle and where the particle
is ejected together with a spin applied to it so it can maintain a
straight trajectory. Remember, the particle is extremely small so it
takes only a small amount of energy to send it on its way. For those
who are aware of the magnetic elevation experiments the elevation
force is a fraction more than the gravity force in the opposite
direction and as many know to keep an article stable while elevated it
is difficult to preventing the elevated article from turning over
which is particle spin. So when the particle is ejected from the
antenna surface it has spin so that it can maintain a straight line
trajectory as well as the ability to negotiate thru areas affected by
gravitational pull which is nullified by the upthrust of the elevation
force created by the magnetic field of the eddy currents. However
these ejected particles passing from one antenna to another does not
explain the transmission of intelligence so something else has to
occur otherwise we are stymied. Well remember that Newtons laws of
action and reaction means there is a reactionary force on the
radiator from the ejection of the particles is similar to what you
see at the swimming pool with a spring board. A diver jumps on the
spring board which is a downward force and the reactionary force is
that applied by the spring board to the diver so in the case of an
antenna it must move in a reaction to the downwards motion and you
then see a repartition of what you saw with the spring board where
after the diver has left it continues to oscillate for a short time.
But in the case of antenna another particle quickly takes the place of
the ejected particle for a place to rest such that the antenna
oscillation continually takes place over a short length of time. To
fully understand this repartition of ejection and replacement with

respect to the natural frequency and time factors we must now investigate further the electrical circuit that simulates such action .This is called a Tank circuit where the energy supplied sloshes back and forth between a capacitor and a inductor and where the capacitor itself cannot radiate and the inductor can cause radiation in two different ways ie. when the field is being generated and when it is dissapating for each full cycle or period of the tank circuit operation. This represents the full sinosoidal of the applied alternating current when applied not to a fractional WL antenna but a full WL antenna because a period represents the repetitive function of BOTH phases of the applied current.
More on the Tank circuit operation in the next Part four. If you can get ahead of the game and study the operation of a tanks circuit you will see it is not as simple as it appears because it involves time constants,
voltage multiplication as well as phase change each of which is important in terms of sequence to provide
for the ejection of particles . I may have to Google to get the sequence correct ie copy the description or refer to a URL for simplicity

Rather than continually posting your beliefs about *why* your Unwin antenna operates, please post some provable evidence about *how* it operates with respect to the fields generated by a standard and well-proven radiator such as 1/2-wave dipole.

A matched, 100% efficient, linear 1/2-wave dipole with 100 watts of applied r-f input power at 3.5 MHz develops a peak field intensity of about 70.14 mV/m at a distance of 1 kilometer, in free space.

> > How does the Unwin antenna compare to this? < <

If you don't know, or you do and it is considerably less than the value above -- then probably there is little point in proceeding with your posts.

RF

It followsa straight line trajectory in two dimensions out of three
The weak force othewise known as the magnetic field of the eddy
current
overcpmes or neutralises gravity while applying spin such gravitation
has little or no
effect on the trajectory as it is projected with spin. This can be
seen with
elevation experiments

hi

this may be an unfair question, but presumably you are running
antenna cable ?? so why can't you attach a small additional
cable? who would notice if you wrapped them ?you'd also have to run a
power cable to to rotor too?

the rotor motor would require power, and i can't see how'd you
supply that wirelessly

so at minimum you'd have an antenna cable and power i would
guess so if your power cable had a few extra conductors who would
know? seems the easiest way

you could buy a wireless relay controlled or build it opening
/closing a relay wireless is pretty easy not sure how your
existing rotor sends position but you could perhaps remote that
or simply add your own position sensors and remote them back
using extra relays or some a/d method

naturally my presumption the rotor is for an antenna if so you'd
have to make your wireless device immune from interference that
your tx/rx antenna might cause as well as interference that
might be caused my your 'wireless controller' device

Minor quibble - the pendulum was a proof, not serendipity. His best known pendulum, at the Pantheon, rotated 11 degrees per hour, making a full circle in a bit less than 33 hours.

> This meant that
> there was another force, a rotational force must be at work over and

The rotation of the earth was the force.

The angular speed could be calculated and proven as:

angular speed = 360 * sin (latitude)

Which is to say that at the poles, the rotation takes one sidereal day, taking progressively longer as one heads to the equator, at which point the oscillation plane stays fixed.

> Thisw is analagous to our year system of time where every four years
> we add a correction to the period of time
> by summing all these slight incorrection of time as a full day in what

More precisely, it is a way to correct our calendar system without major disruption. As the ability to measure time became more precise, coupled with the obvious shifting of seasons as the error in the calendar added up, it was a way to correlate the calendar system with as little disruption as possible. So it is a time measurement accuracy issue, coupled with change in the rotation of the earth. The former is the most significant error source.

> This is the reason for the choice of a full wavelength radiatorl since
> it represents a single oscillation of its harmonics PLUS this small

Now this is interesting. Does it follow that the radiator therefore
needs to change in relation to it's latitude?

In replacing my car antenna I pulled the radio end connector off. It looks like a small gauge wire, plastic sheathing and braided wire. I need to replace the end piece or better yet splice it to the new antenna cable. What type of connector do I need and where can I get it. This is for a 1999 Subaru Legacy. The replacement antenna said OEM but of course it was not The new connector at the mast produced a 12 inch cable that has a single bayonet looking plug and the old one was a round piece the fit over what looked like an rca type plug.

one can easily send power up the coax. One can also easily send rotator
commands.

Whether someone makes this as a buyable thing is another story.

Dave,
Building a tuner, depending on the type, can be fairly easy, sort of. The difficulty level jumps by an order of magnitude if it's going to be an 'automatic' type thing. Not impossible, but certainly much more complicated.

Mobile antennas are more efficient as they get longer in relation to wavelength. Typically that means a big ugly thing for the lower HF bands. An itty-bitty thingy at VHF/UHF. A typical HF mobile antenna is very seldom very efficient once you get below something like 10 - 20 meters or so. Any mobile antenna on 80 meters is very, very seldom more than about 5% efficient at best (actually, more like 1 or 2%, if you're lucky). So, depending on the bands you plan to work, and the length of that unloaded whip in relation to the frequency's wavelength, don't expect very much. Efficiency is directly proportional to 'ugly' and impractically tall on a vehicle.

Screw driver vs. bugcatcher antennas. Below something like 20 meters, the bugcatcher, hands down, except in convenience (changing coil taps). Above 20 meters, or so, almost anything that's close to a 1/4 wave length works pretty good except for those street lights and tree limbs, sort of.
- 'Doc

(It isn't efficiency, as such, that you should worry about, but the radiation pattern, which is definitely controlled by antenna length and height.)

I went to your website but I didn't see any specific antenna information,
like a ham might want to build a new type of antenna, to try it out.

I saw a write-up of an H-F antenna with elements wound into a spiral and
wondered if that might be yours, as you speak of physically small antennas
(fraction of an expected resonant size).

Pls advise in group. TNX.

I have enougth on my hands explaining antennas in equilibrium and you
want me to change course in the middle
and switch to what. you want to talk about! I'll tell you what, refer
to what happens to a current carrying member
as descibed on my page. Now go to a member that is not in equilibrium
and where the external charges move
to one end to meet Newtons law and thus charges in the center which
formally were equal to zero now have a quantitive value.
This states that when equilibrium breakjs down current flowsw in the
CENTER of the conductor.
Start your own thread on that subject while we continue with antennas
in equilibrium

A helix is an excellent example to talk about to arrive at small full
wave antennas.
When you follow the reasoning of the extension to Gaussian law of
statics which makes
it dynamic it brings to the surface that a radiator can be any size or
shape as long as it is in equilibrium.
So to meet the intent of both laws which are now the same, we must not
impose any lumped circuits
while making our antenna. Now a helix is a fractional wave antenna
with added capacitive and inductive
lumped loads, thus to follow the intent of Maxwell's law we must first
extend the antenna to a full wave form
while at the same time cancelling the added lumped loads. So if we
start with a half wave helix in standard form we have to
continue the element in a down ward direction where we then reach the
starting point. Doing this first completes the circuit to a full wave
and secondly it cancels the pre imposed capacitive and inductive
lumped load that are inherrent with a standard helix antenna PLUS we
have removed the need for a ground plane as the completed antenna is
now a full instead of fractional circuit. Now instead of winding with
a helix angle of some ten degrees plus we can now
push the windings close together and then tip the new antenna to a 10
degree plus angle to put the whole thing in equilibrium by replacing
the angular force represented by the form pitch that we removed by
losing the pitch of the winding. Actually this works out quite well as

you can now laquer the assembly where it has no voids and is quite strong.
By the way my antennas are always of a full wavelength which by virtue of its reduced volume then becomes a small FULL wave antennas to retain the inherrent efficiencies of full wave antennas in equilibrium as well as resonant.
Allow me to continu on this line of thinking. It should now be seen that an array is also shrunken not only by the shortened elements but also by the fact that element spacings conform to the equilibrium of the array as a whole! We then have an array that does not have to have elements at certain distance from each other ad infirnitum but just two elements much closer together where all radiation is accounted for!
Hope the above helps you out but I do expect howls of resistance from others as they wish to protect the notion that "all is known about antennas" thus this posting is sacrelidge and must be negated at all costs. And some others ofcourse will vehemently reject the notion of the WEAK force being revealed by a ham where Einstein could no so for me the end of the World is aproaching or at the least the magnetic pole of our Earth has started a full rotation!
Cheers and beers

Art wrote:
"This states that when equilibrium breaks down current flows in the CENTER of the conductor."

Fact is, only direct current flows in the center of the conductor because alternating current makes more counter emf in the center of the conductor than in the exterior. There are more total magnetic flux linkages at the center and voltage is produced by the rate of change of these linkages. So, current drnsity is greater as the external surface of the conductor is approached.

Equilibrium is synonymous with balance or being at rest. An EM wave is never at rest. A "balanced antenna" has equal capacitance to earth from both of its feed terminals. Balanced and unbalanced antennas perform equally well though in application one may be more suitable than the other. A ground plane may be more easily fed by coax than a dipole but both have the same power gain. There is no mystic advantage of equilibrium in an electrical sense, only in contrived nonsense.

Art wrote:
"---thus to follow the intent of Maxwell`s law we must first extend the antenna to a full wave form."

False. All we need is resonance to eliminate reactance which otherwise would limit current in the antenna . First resonance in the thin straight 1/2-wave dipole ia about 5% less than a physical 1/2 wavelength. A full wavelength straight antenna has characteristics completely different from its first-resonance cousin.

A small diameter coil radiates perpendicularly to its axis. As a radiator its effect is related to the coil`s length not the length of wire on the form. Wire length is related to resistance to r-f current and therefore to loss in an antenna containing coils. That is the source of skepticism of the Unwin antenna. Resistance-loaded antennas have proven useful in situations demanding great frequency bandwidth so Art may have something of value after all.

My ARRL Antenna Book (20th ed.) says on page 16-13:
"The general approach has been to use a coil nade from very heavy wire (#14 or larger), with length-to-diameter ratios as high as 21. British experimenters have reported good results with 8-foot overall lengths on the 1.8 and 3.5 MHz bands."

Bill Orr wrote on page 78 of "All About Vertical Antennas":
"In general, a half-wavelength of no,14 Formvar-coated wire is spirally wrapped on the form, with turn spacing approximately eqial to the wire diameter. This amount of wire will approximate a quarter-wave resonance. Orr`s book was first printed in 1986. Unwin has a problem with novelty.

Michael, you are the first to get to the cusp of this discussion by
coming from the other side
relatively speaking by invoking the time difference which when filled
by a force closes the vector circuit reqiered for equilibrium.
Perhaps you can now take over and explain the rest of the story where
instead of lengthening the pendulum the radiator
you instead shorten it to the other resonant point and thus deduce the
shape of the resulting oscillations i.e. less damening. It seams as if
hams are totally enamoured with fractional WL antennas . Such an
escursion is what they want to see first like looking at the last page
of a book to get some commonality to their every day thinking. Will
you do that for me?
Best regards
Art

Yes
I built a 10 meter EDZ Lazy H in 2001 (back when we had sunspots) .
Top wire was 40' up. Measurements were 22' per leg & 22' vertical
spacing. Phasing line (non twisted) was 450 ohm window line. Worked
excellent on 10, 12, 15, 17 & 20. Also used it on 40 where it acted
like a dipole.

It was bi-directional on 10-20. Didn't measure actual gain but always
got excellent reports (5x9+) in favored directions (from Siberia,
Ukraine, etc.) on 10-20 SSB with 100 watts.

The weak force is NOT otherwise known as a magnetic field. It relates
to radioactive decay and is only relevant at distances less than 10
e-8 nanometers and has nothing to do with electromagnetism.

> Best regards, Richard Harrison, KB5WZI

Sooner or later you will have to change your attitude. Terman was in
error by not including the WEAK force such that a radiator was tilted
and you are still clinging to his line of thought. Think about it
Originally I dampened my antenna by using the
pendulum as a equivalent mechanical example and you saw on my page the
resulting change in the oscillations.
Now you can do the opposite if you have a half wave antenna!. So what
has happened? The half wave is still resonant and the circuit has also
changed to a series circuit so we have lost the energy retention
propertes of the TANK circuit ! At the same time we must still retain
the closed system circuit which means the current must also travel
down the center of the radiator! Imagine that As an old ham who can't
change his ways you can create havoc about that.
Now when the charges move down the center of the radiator it cannot
provide eddy currents so the "skin" resistance is absent during that
part of the perioid.
Note by travelling down the center as a half wave it does not need a
counter poise because going down the center makes it a full wave
circuit.
Ofcourse for any other fraction of a wavelength you have to extent the

resistive portion of the center of the radiator in the form of radials so that
the closed circuit is a wavelength or a multiple there of. Instead of the radials in that case you can use instead a variometer so the properties of wave length multiples are retained. Now if you can;'t accept this simple logic ask somebody to use a antenna program to determine the best angle for a vertical to attaim maximum vertical radiation in the same terms that the masters intended with the correct useage of their laws. Krauss did by finding the WEAK force empirically even tho he did not understand why which was why the helix radiating portion is at an angle with respect to the earths surface.Note He also proved that a radiator need not be straight by experimentation without resorting to Gauss when the dynamic extension is applied
Use of any antenna computer program will produce this same angle with straight radiators unless preguided to a planar form! So Richard, saying it is a myth or a fraud is probably O.K. for you because of your age, but for the younger engineers thay cannot afford not to change and be left behind in the search of knoweledge. So no further debate or auguements are necessary between you and I. And I will try to remember to send flowers when the grim reaper appears at your door where your position on antennas will matter no more while the rest move on
and it is only the copper losses or resistance we have to deal with. Richard, you can;'t mess with mother nature or the Universe

Wrong again!
You are following the errors of the past again. Yes, the particle that
```

is
projected away from the radiator is radio active in terms of a
fraction of its life.
And yes the distance that the madnetic field resulting from the eddy
current is limited
as seen with the common elevation style experiments. The distanbce
required for the
velocity of the partical is NOT a determination of distance travelled
according to
Newtons laws of motion. I hope you are not teaching this stuff so
people can get a degree.!

First things first, Arthur.

Why do you persist in posting and defending your unproven and zany beliefs about equilibrium, particles etc that you suggest apply to your "Unwin" antenna, if you don't even know how the free-space radiation envelope from your Unwin antenna compares to that of a proven reference radiator, for a given applied power?

The RADIATION performance of a transmit antenna should be considered before everything else. Even a 1:1 SWR at the "antenna" input terminals over an infinite bandwidth means ~nothing if very little to none of the r-f power applied there is radiated in the form of an EM wave.

Why should any serious investigator be interested in reading about how you think your Unwin antenna operates, if you can't *first* evaluate, publish, and scientifically defend its free space radiation characteristics as compared to a known standard radiator, such as that of a resonant, center-fed, 1/2-wave dipole?

248. series circuit for fractional WL antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-09 23:02:54 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <dc9bf3a9-bdc2-4474-bfb1-64157c48f94b@z72g2000hsb.googlegroups.com>
Source record: 24321

I would like to add a caviate to assigning a series circuit which I
did
to follow convention for fractional WL. If I had a lab it would be
easy to prove whether the distributed capacitance
and the distributed inductance are themselves in parallel within the
radiating member instead of in series
such that the energy retention qualities are kept. And possibly this
circulatory arrangement will supply some connection to the swerling
eddy currents upon the surface. However I will keep to convention
until the corresponding evidence comes in. Got to get the DC
resistance of a radiator involved to resolve that one.

Believe me they will. To follow theories as being correct without
your own personal study is to become a lemming
I suspect you are still holding on to the Quark and "W" theory
of Feynman but as yet I don't believe one iota of evidence has been
found
that declares their presence or the actions that he predicted.
Theories really
depend on your academic stature and the power of perswation. Remember
people such as Green had little education but achieved fame without
being a lemming.
Same goes for others in the radio field whose work was purloined by
others.
When the corrected books are published will you leave college in anger
or do what all
instructures do and tell the students to buy new books every year at
high cost
and pretend you knew all along? Not once have you successfully evoked
the laws of the masters
to bring my logic to a halt. Everything you have stated has been
incorrect or faulty us of known laws

Yup, it is difficult, But I trust my logic in the face of contrary
statements that have no logic.
How can anybody supply a theory based solely on mathematic
tumbles..... but they do.
How can people who oil tractors and the like on road building and
nothing else and
call themselves engineers,...but they do. Some engineers put a wig on
their heads
and from then call themselves judges.....but they do! Some
people unlock the doors
of a radio station every morning and call themselves broardcast
engineers no less
.............but they do!

So basically it's your contention is that everything I say is wrong.
Ok, you're right, Art. :-)

Well, I'm good with the cheers and beers, but no way am I close
to clipping and snipping (wire) to make an Unwin Antenna.

What do they look like? Photos? Diagrams? Crayola drawings?

Don't get me wrong, OM, theory is important but there's no textbook
that loads up at 7220 KHz. Show me some metal parts.

I am sharing information with all so there is nothing to stop you
making one for your own use.
I really want the Britts to use it on their small gardens at the back
and get on the top bands.
They are still into experimenting oiver there where America still is
in the throw away society
preferring the Lazy Boy and a six pack instead of a hobby. All they
want to be is LOUD and talk over the other cb ers
which is why their interest in antennas evolve solely around gain and
a amplifier.
Read some of the postings and eventually you will find where it tells
you how to make one as I am not giving them away
for trial runs on the air. Just follow what is evident, a radiator can
be any shape size or elevation as long as it is in equilibrium.
Put another way if during construction you add lumped loads in any
form then they must be cancelled. Now let your imagination run wild.
I have made one in sheet form so there are plenty of options

Tell you what, get some wire twice the WL of the frequency you are
interested in.
Wind a close coil any diameter with it until half the wire is used
then change direction and come back
without changing wire winding direction and wind the wire on top of
the first coil where you finish with two wires to feed.
Put a variometer in series with it and then get on the air. Now this
is not exactly in equilibrium because one coil is a larger diameter
than
the other. Nor is the wire pre twisted pair which nullifies near field
noise to my thinking. Now you have a helix style antenna but without
the helix.
Coat the antenna with an alkyd type solution before you slide it off
the tube since the inside coil must be exposed the same way the
outside coil is exposed
'So it is easy to build a common standard form as stated on my page. I
really do not know what the beef is. Alternatively make a zig zag with
your wire two times and connect the wires at the top so you have two
laminations,. Be inventive and don't throw your other antenna away.
Hams in the past have tested their new antennas only to get insulted
over the manner of testing so a ham should never make claims regarding
gain

So far I have been right!. You are excercising free speech without
scientific underpinnings.
You like others did not come forward and prove scientifically that
Gauss law CANNOT be extended.
You dont accept the idea of a partical with nuclear life. In fact you
don't even accept eddy currents.
If you are teaching kindegarten then such free speech is in order as
they will not challenge you.
But you must expect challenges from grown ups unless you supply
underlying data for claims made
or refuted. I will now give you a chance to show what expertise you
have.
Professionals in antenna design work mainly in the higher frequencies
where they show circular
eddy currents on the internal wave guide walls. So why on the lower
frequences do amateurs deny
the existance of surface carried eddy currents? This same scientific
fact is used in detecting material flaws without destruction
as fissures in metal alters the eddy current. So where in the hell are
you comming from and where does your main expertise dwell?

John, thank you for that. Over the years he has hinted that he was a
assistant professor at a local college
but as of late I have found it hard to fathom things out as he is so
lacking in the field of physics and electrical
engineering but I gave him the benefit of doubt. So it is quite
possible that like Richard he has his moments.
Like going to the bedroom for a clean shirt. forgetting why he came to
the bedroom so puts on his pyjamas and gets into bed
lesving his wife already to go out while he goes to sleep. I think
they call that senior moments. Well the info given clears a lot of
things up
for me and I shall not continue to guess where his expertize is any
more.
Regards
Art

Yup, I felt sorry for him, especially when he was attacked for being
Jewish
But from what I understand fractals are being used as embedded
antennas
and in other areas of the military so he must be laughing all the way
to the bank
while other hams continued to cry fraud because all they was
interested in was more gain
to become loud mouths.
I wish him well

Have you tried lengthening or shortening the line by about 4 1/2 feet? It may be simply that the length of the line is resulting in an impedance your tuner cannot match.

I think, given the nature of the antenna and the length of your line, you can probably expect about 3 dB losses on a dry line and close to 10 on a wet one.

You are offering DC antennas?
How do you match them?
Are you sure, your cables and connectors don't leak and spill
direct current to the environment?

Take one wavelength of zip cord. Wrap it around any diameter form, as
distinctly specified above by the authur. Half the wire is used
going, and half the wire is used returning by specification of the zip
cord, as distinctly specified above by the authur.

There is no change in winding direction as zip cord guarantees this by
physical attachment, as specified above by the authur. Both wires are
wrapped without changing direction, as distinctly specified above by
the author.

There is no pre twisting for the same reason (which might nullifie
near field noise to his thinking - an asset to almost anyone else, but
go figure), as specified above by the authur. It is exactly in
equilibrium because both coils are the same diameter, as distinctly
specified above by the authur.

There is no need for coating as there is no inside coil, this is
guaranteed by the physical construction of zip cord. Zip cord also
guarantees equal lengths of going/returning lengths of conductor.

Short one end of the zip cord paired conductors to make the gussian
loop, as distinctly specified above by the authur.

Feed the other end of the zip cord paired conductors to emit the
neutrons' weak force, as distinctly specified above by the authur.

Performance will follow the principal physics of this weak force and provide an intensely weak signal. If your listeners experience received signal levels greater than -40dB compared to a standard (non-gussian) dipole, then you have not followed instructions distinctly quoted above from the authur.

Careful attention to detail can achieve increased performances of up to -60dB below traditional designs (indistinctly specified by the authur).

Take care to note that this design is impossible to model as it violates every software package's capacity to allow closely spaced wires. There are absolutely no software products, nor freely available packages that perform this analysis - you are now in faith based alchemy. Any claims to the contrary (contradicting this faith based illusion) are delusional. This level of delusion can be confirmed by the whole absence of reference, citation, or offering of results of double-blind testing.

Not that I have any confidence in Art's antenna design. But you wind a
cylinder with zip cord from left to right, with the left end pair being
the feed and the right pair shorted (as if a single 2W wire) then the
'return winding' will essentially be wrapped in the opposite direction.

This URL, of a patent of an antenna which is growing in commercial use, describes just such a winding and how it is constructed for real world use. I am almost positive this is the "double helix winding method" which Art is making reference to:

http://www.patentstorm.us/patents/7187335/fulltext.html

In particular, this reference in the patent:

"It has been found that interlacing a false winding into a current enhancing unit (such as the top unit winding shown in FIG. 6) or a radiation resistance unit (such as a helix as shown in FIG. 7) enhances the bandwidth of the top unit as well as improves the current profile along the antenna. The interlaced false winding has little effect on the resonant frequency of the antenna system."

Well if you do wrap in one direction and then immediately wrap in the
opposite direction upon each other, I wonder what the cancellation db

figures are. On the other hand if you should wrap in the reverse direction with some substantial spacing, I could imagine that there might be some gain although very small??

Here are a few definitions for you of "caveat", from this URL
"http://www.google.com/search?hl=en&q=define%3Acaveat&btnG=Search"

caution: a warning against certain acts; "a caveat against unfair
practices"

(law) a formal notice filed with a court or officer to suspend a
proceeding until filer is given a hearing; "a caveat filed against the
probate of a will"
wordnet.princeton.edu/perl/webwn

Caveat (foaled 1980 in Maryland) was an American thoroughbred stallion
racehorse. Bred by Ryehill Farm, he was sired by Kentucky Derby winner
Cannonade out of the The Axe mare, Cold Hearted.
en.wikipedia.org/wiki/Caveat (horse)

a warning; a qualification or exemption; a notice requesting a
postponement of a court proceedings
en.wiktionary.org/wiki/caveat

If a caveat is lodged upon a title to land it indicates that another
party other than the owner claims some right over or interest in the
property.
www.aussie.com.au/Glossary.htm

Is a document any person with a legal interest in a property can lodge
with the Titles Office to ensure the property is not sold without their
knowledge
www.malenyrealty.com.au/resources/technical_terms.html

A note placed on the register in the Land Titles Office at the
instigation of a person who claims a certain interest in the land. In
BC, a caveat remains in force for only 2 months, then lapses.
www.propertytours.ca/realty/glossary.htm

A warning; a note of caution.
www.id.uscourts.gov/terms-cd.htm

"Beware" ï¿½ if a caveat is lodged on a title to land, it warns a person buying the property that a third party (party which lodged the caveat) has some right or interest in the property.
www.efame.com.au/glossary.htm

A warning on a title to a purchaser that a third party might have some interest or right in the property.
www.reinz.org.nz/reinz/public/buyers-sellers/terminology.cfm

A formal notice, that asks a court to suspend action until the party which filed the challenge can be heard.
www.boise-idahos-real-estate.com/real-estate-definitions-c-158.html

a formal notice given by someone to prevent the proving of a Will or the grant of administration of an Estate.
www.oceancountygov.com/surrogat/glossary.htm

means a document lodged with the Recorder of Titles by a person authorised to do so forbidding the recording of any dealing on the title subject to the caveat Literally means beware. In real estate, it warns persons (prospective purchasers, mortgagees, etc. ...
www.cromer-partners.com.au/pages/glossaryalpha.php

A notice of warning given to a public authority, eg Titles Office, claiming entitlement to an interest in certain land. The caveat is registered and remains on the books as a warning to anyone who contemplates dealing with the property. ...
www.redearthfinance.com.au/bwWebsite/followon.asp

A notice on title proclaiming a possible interest other than that of an owner.
www.talkproperty.net.au/index.php

A notice given to a legal authority not to do something until the person giving notice can be heard.
www.recalgary.com/information/glossary_c.htm

A legal notice by a person having a (caveatable) interest in the property which will prevent transfer in title until the claim has been determined.
www.eastcoastconveyancing.com.au/glossary.htm

Latin for "beware". Usually it is in the form of a contract clause that stipulates a particular requirement.
www.yourfinancechoice.com/index.php

If an creditor of the estate of a decedent is apprehensive that an estate, wither testate or intestate, will be administered without the creditor's knowledge, or if any person other than a creditor is apprehensive that an estate may be administered, or that a will may be admitted to probate ...
pages.jbiproperties.com/ezrealestateoptions/glossaryofterms.html

a formal notice or warning against certain actions being taken by a court; most often seen in regard to the granting of probate of a will by the court; most common usage as a document that is filed in the Land Titles Office to warn of possible title defects;
www.manitobacourts.mb.ca/definitions.html

A notice not to do something until the person caveating has been heard. It is often seen in the case of land claims, where a caveator might object to a claim overlapping his own. ...
www.genfiles.com/legal/legalterms.htm

Latin for ï¿½bewareï¿½. This often applies to a contract clause
www.interestrate.com.au/glossary.asp

This indicates the rights or interests of a third party in the property. A caveat is a legal document which, when lodged in the Land Registry Office, gives the caveator the opportunity of protecting an existing right or of establishing an existing claim in property. ...
www.virtualrealty.co.nz/reterms.html

If you don't pay your fees, you may find one of these registered against your title. This ensures the corporation gets its money before you dispose of the asset and may be the basis for collection procedures.
www.calgaryselect.com/Housing/Condominiums/Glossary/tabid/100/Default.aspx

Quite interesting, the fact you were being "fooled" into thinking there was but one! <grin>

BTW if you split the 2 zip cord wires apart you could construct a loop
antenna, in just about any configuration you wished.

Hi Art -

Where am I coming from...well, a cab driver in London sent me a note a year or two ago after I came to your defense in this newsgroup. He confided to me about something that I had already suspected regarding your condition. Since then, I have advised some of your antagonists in the group by email that it might be the better part of valor to take it easy on you and just let you have your say. Mostly, I just wished for you pursue your interest and to avoid embarassing yourself.

Not that it matters, but my main expertise as it pertains to this discussion is in the design and construction of electronic equipment and scientific apparatus used for the measurement of various physical phenomena. e.g. US Pats 5,018,382 and 7,119,588. In the '70's and 80's I was in the business manufacturing guitar amplifiers. Among other things, I am an amateur radio operator and a musician.

For the record, although I have disagreed with you, I have never been personally disrespectful to you. I believe gentleman should be able to disagree without being disagreeable (or insulting).

The authur is quite distinct. Zip cord perfectly enforces the
original specification of winding direction. Any confusion that
results is not expressed by the explicit statement from that authur
above.

Further, results of supremely weak performance confirms this and has
been experienced by many (including Guss himself) for more than 3
centuries now.

We aren't talking about "any" antenna, just those with superior weak
force performance due to neutron emission. It's all there on the
page, just read it!

You are disgusting.

Your manner(s) and depths you would stoop to are below a minimum level
to engage in human dialog/relations.

I find it a shame you would even be granted a license to engage in
communications with decent human beings--it certainly is to the
detriment of amateurs worldwide ... you sir are a NUT of the most
despicable kind--and, clear proof the bar should be raised!

However, I can only wish that you remain within the ignorant confines of
the prison of your mind; to awake to the reality of what you really are
could prove fatal and the undoing of your insane ego ...

PLONK!

Correct. And if zip wire is used then you are adding a lumped load
which is a violation with respect to equilibriu,

Art wrote:
"If I had a lab it would be easy to prove whether the distributed capacitance and distributed inductance are themselves in parallel within the radiating member instead of in series such that the energy retention qualies are kept."

J.C. Maxwell, also an Englishman, had no lab.

Radiation is the function of a radio antenna. Kept energy is not so important.

Recall that Maxwell`s great speculation was that displacement currents generated a magnetic field the same as conductive currents. Later, this was proved beyond doubt. It is a radiation requirement as no conductors inhabit empty space.

My edition of the "ARRL Antenna Book" is the 20th, which means its contents have been refined and tested over many years. It says on page 2-6:
"Now we just compared the antenna to a series-tuned circuit. Near its half-wave resonant frequency, a center-fed lambda/2 dipole exhibits much the same characteristics as a series-resonant circuit."

J.C. Maxwell died in 1879 at an age of 48 years, 8 years before Heinrich Hertz generated the first man-made intentional electromagnetic waves. These proved Maxwell correct. Oliver Heaviside, a Scot, born in 1850, decided to teach himself the contents of Maxwell`s "Electromagnetic Theory" and in 1887 started "dumbing down" Maxwell in a series of articles published in an English magazine, "The Electrician". That was the beginning of modern communication engineering.

Oliver Heaviside once said, "Let mathematics be humanized if possible. The best of proofs is to set out a fact descriptively so that it can be seen to be a fact."

Heaviside proves that all who are born in Edinburgh or London are not fools.

Best regards, Richard Harrison, KB5WZI

What you are refering to i believe is the Rhode Island antenna that
has been attacked
by all of ham radio but again it could be another follow up new
antenna tho it seems a bit soon
since they had to resubmit the first patent to get it accepted.
John, imagine the following
1 a rcp and a lcp helix driven in parallel with counterpoise. What
would the ensueing gain consist of?
2 a rcp and a lcp helix driven antenna connected at the top and fed
with out a counterpoise (assumption is that windings do not come in
contact with each other)
What would the ensuing gain, if any, consist of ?
Would either 1 or 2 produce a negative total gain?
I am really having a difficult time understanding why hams THINK so
bad of this type of antenna, with close windings or in pitched form

You just can't stop wire radiating so where are they coming from?
Regards
Art

Regards Art
Nobody has supplied any reasoning of what radiation a ham could expect
from such an arrangement. Yet anybody can check it out forthemselves
without unsubstantiated off the cuff comments meant to inflict pain

It is the "Distributed Load Monopole" (DLM) antenna by Robert Vincent ...

I have a 50 ft. one in my front yard and disquised as a flagpole, for 80m.

At the back of the house, and hidden from view, is a 1/2 version for 10m.

For me, it is a perfect design ... I have not incorporated the
"interlaced winding(s)", yet ...

Regards,
JS

Please accept my apologies because I have disrespected you
Regarding my findings they have been partially checked over by
qualified people
and it has taken a long while to get to this point.
If you will accept it I would like to send you an antenna as a gift
but I do not want personal favors of any kind.
Frankly it is the responders that need thought as they do not present
any scientific underpinnings for their statements
that I can respond to in kind Unfortunately I do sometime get caught
up in the hate and respond in kind which I should not do
Believe me Jim all those that poo hoo what I am sharing will rethink
their motives when it is recognised by academia which is really the
only road for acceptance available to any lay person with respect to
ham radio. As the numbers of silent keys mount the majority in ham
radio will not be comprised of people with open minds and curiousity

and changes will reflect the change in demeanor as has already
happened on this newsgroup. I don't think the days will ever come back
where antenna science can be discussed civilly and logically anymore
per the intentions of the formation of this newsgroup founders since
lack of civility is truly a virus that can over take us all
Regards
Art

There's a profound old saying that I'm occasionally reminded of:

There, but by the grace of god, go I.

It has a sobering effect. And I hope there will be a kinder and more patient soul than I to help me stay on track someday when I need it.

I would be honored to have one of your antennas, Art. I promise I'll try to figure it out.

The zip cord is in true equilibrium for any winding. What you
describe is twisting and this violates equilibrium. That won't work,
and Guss has demonstrated this three centuries ago.

James Clerk Maxwell was a Scot, born in Edinburgh and buried at his
family home in south-west Scotland, less than 50 miles from here.

Now can we please shut this discussion down? The sound of Maxwell
turning in his grave is keeping this whole county awake.

Hi Jim

Sir
You are a gentleman toff and a scholar.
This was a compliment paid by east enders of london in years past to
a person who stooped to give a helping hand to some one of a lower
class.
Thank you.

That is as I remember the above is verbatim the email that was sent
to you, I think it is despicable of you to use something sent in
confidence and twist what was written and use to attack.
An enquiry was made as to the meaning of a post you had made and the
above was the reply in totality.

You could always use a lumped element model, but be sure a balun
is not included, in order to maximize radiation from the coaxial feedline
shield.

Bluey and John Put a stop to this and put the whole thing behind you
Tomorrow is a new day where I am going to make a new antenna the
receipient
of which will be free to discuss at his leasure when listerners can
determine for
them selves whether I should be put away for suggesting that I had a
real antenna.
Going out of town with my wife for a couple of days so don't
misinterprete my absence.
I am in good shape hiccup,hiccup burp so there are no problems of any
sort at this QTH
Have a great weak end or weak force
Art

All other faults about Arts antenna ignored it is obvious he has not considered the losses of the cable he is using to fabricate his antenna. Zipcord is far from being a very good transmission line. I have melted it while tuning a 75 watt transmitter into a light bulb. The graphs on his website show pretty much what one would expect feeding power into a very lossy cable. Yep it looks like he built himself a very poor dummy load.

As a matter of fact I believe his discription of his wonder antenna very closly describes a method of jury rigging an emergency dummy load. The only thing else needed is a bucket of water.

Now wait just a minute, Richard. I think it may depend on the zip cord
you use. Some of the zip cord, when close wound, will have more
dielectric between the interturn wires than between the 2 wires of the
zip cord itself. Of course it _can_ be rebalanced if the air gap
impressed into the plastic during manufacturing is the correct depth.

My transmission line is Andrews..7/8 'dia. I dont use zip cord
You say the graphs depict a very lossy cable, can you give me a
reference that points to that?
Always willing to learn
And another point, where does this notion come from that a closed
circuit of one WL will always creat feed line radiation?
I have been of the opinion that with a balance to unbalanced jobby at
the antenna there is no radiation at all from the feed line and if you

use
open wire the jobby is not required. Another point where can a dummy load be found with several resonant points and anti resonant points with poor SWR in between? Another point what is the real capacitance of zip cord per foot? Seems like somebody is not seeing that as a lumped load ....curious.
Another point I can model two helix antennas, one LCP and one RCP connected at one end and so could Kraus and so can the space engineers!
The idea you cannot model close spaced lines when unlimited segments are available seems to be inaccurate to me.
The idea thatr two helix antennas provide negative gain means somebody is drinking.
Note the idea that radiation can some how be cancelled seems wrong to me. I just can't see two particles with like magnetic fields cancelling each other
Seem like a lot of wierd speculation is going on with nothing to suggest that they are reasonable.

Who cares about all that irrelevant jibber jabber. It means nada
in the overall big picture of the universe in the land of Obama.
Your loading losses are what's going to ruin your day at the test
track.
Your antenna is pretty much nothing but a perverted, *very*
inefficient thin 22 gauge wire loading coil fed on the low frequency
of 1.8-2.0 mhz in your recent case.
Any delusions of performance grandeur would tend to imply that
the designer must be drunk. *hic*

> Seem like a lot of wierd speculation is going on with nothing to
> suggest that they are reasonable.

Yep, that's your "Articles" alright... Weird speculation backed
by nothing to suggest the speculation is reasonable.
Onward through the fog. :/

Negative contact on that Artmobile... Breaker 19
for a radio check!
Academia means little to me in the case of "new science".
Real world tests with real word results of the tests are the
only thing I care to see when concerning "new science" antenna
schemes.
You can't brown the food if you refuse to stick it in the oven.

No but the antenna is made of zip cord.
> You say the graphs depict a very lossy cable, can you give me a
> reference that points to that?

The fact that the VSWR keeps decreasing with an increase in frequency
is characteristic of a lossy transmission line, In this case a lossy

antenna.

> Always willing to learn
> And another point, where does this notion come from that a closed
> circuit of one WL will always creat feed line radiation?

Where do you get the notion I had that notion

> I have been of the opinion that with a balance to unbalanced jobby at
> the antenna there is no radiation at all from the feed line and if you
> use
> open wire the jobby is not required

. Another point where can a dummy
> load be found with several resonant points and anti resonant points
> with poor SWR in between?

Yes but the anti resonant points are not very pronounced. Like I said
its a poor dummy load. A poor dummy load because it still has
reactive components. Its still a better dummy load than an antenna.

> The idea you cannot model close spaced lines when unlimited segments
> are available seems to be inaccurate to me.
> The idea thatr two helix antennas provide negative gain means somebody
> is drinking.

Who said you have two helix antennas, They certainly are not as
defined by Kraus or anyone else. A helix antenna is more than wire
wrapped on a stick.

> Note the idea that radiation can some how be cancelled seems wrong to
> me. I just can't see two particles with like magnetic fields
> cancelling each other.

The fields created by a moving charged particle can easily cancel that
of a like particle, they just have to be moving in opposite
directions. Wire wound reduced inductance resistors have been made
wind the wire and connecting it much as you have in your antenna.
Again you discribe a dummy load

> Seem like a lot of wierd speculation is going on with nothing to
> suggest that they are reasonable.

Perhaps you forget I actually made your antenna. All it did was get
warm. It worked best when the input to the transmission line was
shorted and fed as a random length of wire.

Since you claimed it worked on VHF I actually attemted to make a
contact using it. I live less than 5 miles from a repeater and can
usually get into it with milli watts on a hand held. I couldnt get
into it with your antenna with 10 watts. I was afraid to use more
power as i may put my radio at risk.

The fact that I could place it in a metal locker and operate it with little change in VSWR indicates most of the power is being consumed by a resistive load. The signal is being radiated but most of it is being changed to infra-red radiation first.

If you dont believe me just build the thing and test it for yourself comparing it to a simple dipole.

I also tested it on an Anritsu antenna analyzer. The results were very similar to what you posted on your website so I am assuming you did something similar to get your waveforms.

These waveforms are also very similar to the waveforms of the improvised dummy load I mentioned so I could equally assume you are a troll and practical joker.

Jimmie

OK, I can do most of that. However, I went to your page for some variometer details, as I don't have one. No luck. From other reading it appears to be a loosely couple balun or un-un. But near there on your page, I discovered some verbiage about building an antenna and saw the reference to a 12-inch diameter. Good find, as I was going to go smaller.

If I wound the thing on cardboard (like a big empty ice cream tub from the ice cream store), could I avoid having to take the coil(s) off the form? What about a paint bucket or an empty pool chlorine tub? I'd sorta like to skip that alkyd step. Messy.

Need more variometer data, but I'll dig for that

Art,
I can say that you've finally gotten something right. If academia does recognize and second your theory, I know that I would be more apt to consider it. Why? Because 'academia' is going to include those who know what the @#$$ you're trying to say. They are not likely to 'condone' something that's not 'right'. And providing the usual proofs to academia would seem like the smart thing to do (like it or not). Is that the most absolutely bestest way of doing things? Toss-up on that, but certainly better than what you are doing now.

Kun katsoo n�it�keskeisimpi� nettilinjo, niin alkuun n�ytt�� silt�, ett� t��ll� palloilee l�hinn� "ruinruinit, muiden mollaajat, ja ostetut ydinlobbarit". Eli suoraan sanottuna yht� tyhj�n kansa pelailevia palloilijoita. Mutta siten huomaa miksi ihmiset t�nne niin mielell��n tulee viisaukasia silti lukemaan?

Jos osut talous-, yhteiskunta- ja poliittiselle sektorille huomaat, miten siel� toimii my�s porukoissa suoranaisia "kassamangneetteja". Olen avoimesti kiitellyt mm Rauno Kankaan miten kristalloisin. ..no hei vaikka "eettist� asennekoulutustyyli��n". Kaveri jos kuka on ollut oiva esimerkki siit� miten nettiammattilaisen tulisi k�ytt�yty�. Aina asiallisena, kaikesta "oskukarstasta" huolimatta tied�t saavasi tukun paikoin jopa el�m�� suurempaa osviittaa ja paikoin jopa nerokasta osviittaa siit� miten maailma makaa kritiikkiin asti. Oivan ja loisteliaan materiaalin saat t��lt� ilmaiseksi, neuvoja on tuohtumaton j�m�k�n asiallinen. Hienoa, juuri t�t� tuhannet t��lt� haluaa.

No tottakai ei finetti tyyli ole j�tt�nyt kylm�ksi, vaan h�nen vision��risyytt��n sitten kopioidaan my�s muutamissa muissa osastoissa, ja hyv� niin. Tietysti kopio on kopio, mutta tusinan verran t��lt� l�ytyy sellaisia kirjoittelijoita, joista heijastuu Raunon oivallinen esimerkkijatkumo. Ja jopa kyky kampittaa my�s Raunoon liittyv�t pakolliset h�irik�ainekset. Joita voidaan mainita yhteisnimill��n, "Oskut, ydinklingonit ja vastaavat". Er�s henkil� jonka sattuneesti haluan ilmoittaa t�ss� on nimimerkki NEO. H�n ei toki ole talous-, poliittis-, yhteiskuntasektoreilla tietysti esikuvansa luokkaa, ei toki. Mutta kampittaa kyll� muutamilla sektoreillaan my�s suvereeneill� erikoisaloillaan. Ja totta kai taitojensa h�ikimi� ns. "ydinklingoneita ja SUPO-sotkijoita on toisinaan niin suuret parvet kintereill��n, ettei rahanjaolla tunnu TVO/Posivalla olevan rajoja h�irikk�sahureittensa palkkaamisiin. Mutta siin� NEO on kyll� kykyis� Raunon rinnalla toki, ett� ammattiviisautta, viile�� asiallisuutta ja ennenkaikkea loputtoman ammattitaitoista materiaalia saamme saavikaupalla k�ytt��mme!

Suuri yleis� nauttii ja nettioperaattorit kiitt�� valtaisien hittim��rien aina vaan jaksaessa yll�tt��. Netti el�� kiistatta vain muutaman t�llaisen "gurun" �lyn neuvokkuudella. Kansanmassat saa mit� haluaa. Ja operaattorien maireat ilmeet kertovat valtaisien suosikkim��rien alati pit�v�n systremit hengiss�. Ennenkaikkea koko t�m� kaikki yhdess� n�kyy aivan k�sitt�m�tt�m�sti kumuloituvine kansan ymm�rryskykykasvuina. Nyt on massoilla kanava k�yt�ss�, jossa ei iso raha pyki. Ei valtiomoinoliitit kuki seinill�. Vaan asiafaktan kiinisaanti on huomattu iloisesti jopa laajasti rajojemme ulkopuolelle asti. Kuten hyvin tied�mme asiallista kritiiki� ei valtiomonopolit salli. Ei SUPO/TVO/kuin edes hallitusmokailijat eduskunnan

helsinkil�is�kyj� my�ten. Nettien palstat pursuaa JUURI t�st�, ett� on maamme ehdottomasti viimeinen vapaamman tiedon periferia sitke�sti. Jopa niin sitke�sti, ett� SUPO/NSA/STUK/ TVO/Posiva/Fortum /GTK ja monet , monet muut uhkailevat aivan h�rskisti tappaa koko kanavan! Heid�n edustamansa valtiorappiollinen m�d�nn�isyys kun ei kansan viisastuessa ja tietoa saadessa en�� totuuksia sied�. Sis�ministeri�n tuhatp�isen poliisisikailukulttuurin uhka on jo pitk��n ollut nettituhoa hautomassa. Saa vaan n�hd� kest��k� systeemimme nimenomaan Suomessa totuuden puhujia?

>suggest that they are reasonable.

Speculation is, what speculations "seems." Your appeal here for
validation suffers from its thin content and over elaborate
speculation. Ultimately, this speculation of yours collapses from
many faults, two of which are enough to describe:

1. This is due to the lack of equilibrium by your own admission of
twisting the line in flagrant contradiction to how you described its
construction.

2, You cannot defend against the poor performance of Weak Forces that
dominate your own design; by your own stated purpose and admission.
This is obvious on the face of it.

These demonstrate the superiority of conventional dipoles and the
experience of millions of users for three centuries confirms this.
This last observation is NOT speculative, but clear proof supported by
a reservoir of data.

>power as i may put my radio at risk.

This confirms at best -40dB of gain attributable to the authur's
design in comparison to a conventional design.

If Jimmie failed at anything approaching the perfection of the
authur's design, is that it does not exhibit an even greater figure of
-60dB - however, it is implied in Jimmie's hesitation to raise power
lest the authur's design burst into flames due to the Weak Forces
dominating the lack of conventional radiation.

Seeing that the authur has admittedly and expressly designed this
antenna to optimize the Weak Force, it would be surprising that any
other outcome would be expected. For these past few months he has
offered no other results of measurement, again admitting that he has
no "laboratory" (equal even to Jimmie's resources). Hence it follows,
that only speculation is available in the authur's defense.

Art wrote:
"Another point I can model two helix antennas one LCP and one RCP
connected at one and and so could Kraus and so can space engineers."

Art should look at page 66 of the 3rd edition of Kraus` "Antennas". Fig. 3-8(c) is the axial-mode helix, an end-fire or traveling-wave antenna. Here the diameter of the coil is a significant portion of a wavelength and the distance between turns (6 are shown) ia 1/4 WL. Large loops (turns) are required to make radiation broadside to the loop instead of having a null there as in small loops. One would usually not characterize the axial mode helix as small, though two of them wound in opposite directions will indeed peoduce both both circular polarizations. Such an HF structure wouldn`t fit in two ordinary shoe boxes. Small-diameter coils produce linear polarizations in parallel with the coil axis.

Best regards, Richard Harrison, KB5WZI

That ius correct but I am interested in small antennas so I wound both
helixes on the same former and at the same time.
Since like magnetic particles cannot collide I must assume that no
radiation is being lost.
The largest diameter I have used so far ius about a foot. The smallest
diameter I have wound was on a hoola hoop and the flatest one that I
have made was
8'" by 12" by a wire thickness which can be wound up in a roll and put
in a sock no less.
I am not a lier!

There have been some suggestions that the sun is not behaving normally with respect to the sunspot cycle. There was a thread in this group a month ago with the title, "Sunspot cycle more dud than radiation flood." If you're worried about that, you might want to have a look at http://science.nasa.gov/headlines/y2008/11jul_solarcycleupdate.htm?list174385.

Source record: 24243

Is there any software available for measuring S/N and signal strength, through the soundcard? My idea is to analyze signals arriving from my antenna, through the receiver and the soundcard, and thus compare antennas numerically in terms of signal strength and noise.

This capability is already present for the most part in the Faros beacon monitoring software, but it is tailored to monitoring only the IARU/NCDXF beacon signals.

Hi all,

I am working on an application of transmission lines for use in magnetic resonance. I know I have seen in the past pre-made transmission line that has an inner conductor surrounded by a white insulator (I think it is Kel-F, it may be teflon) and a copper layer on the outside. It is quite stiff, and comes in long pieces that can be bent with a little effort. Does anyone know where I can pick some of this up? I have been through about 200 google pages with no luck.

Thanks

From its size, I would expect its performance to be less than that of a dipole made from two "hamsticks". But, that may be enough.

Best regards, Richard Harrison, KB5WZI

The variometer allows the frequency to be moved as a multiple of a
wavelength.
Thus allows your antenna to vary as you turn the knob on the radio.
If you do not use a variometer then you just have to hope that one of
the many suitable swr points rest
upon your frequency of choice. This can also be simulated by a series
of jumpers or a slider method
over the surface of the windings. For me I prefer a variometer since
the motor drive can be that which is dismantled from the radio's tuner
such that you have an automatic set up the same as the new variable
antenna that hit the market a few years ago except this design
is less than $100.....big difference.......and much much
smaller....... and yes the variometer is placed on the top of the
tower with your 160M
rotatable antenna. Don't know where I will go next! Sweaty...need a
shower

Tnx Tom, why are there a number of folks totally occupied with trying to keep the rest of us worried? If it's not the tree huggers and their carbon footprint, it's some other condition that implies the end of life as we know it. Could it be that they are intent on keeping us from noticing the guy behind the curtain?

You haven't mentioned the frequency at which you want to make the measurements. Techniques vary with frequency, and the significance / nature of some noise sources is also frequency dependent.

Measuring S/N ratio is somewhat easier than measuring signal strength.

Nevertheless, there are ways to measure absolute field strength. FSM (http://www.vk1od.net/fsm/) provides a method that uses a known antenna and known receiver to measure field strength in absolute units. Along the way, it calculates receiver input power which might be of interest.

NFM (http://www.vk1od.net/nfm/) was specifically written for noise figure measurement using the Y factor method.

Spectran might well provide a first up simple solution to your needs, here is a note on using Spectran for assessment of weak signals: http://www.vk1od.net/gt/nfisa.htm . Keep in mind that S/N ratio is key to copying another station, but the N term includes your noise environment which may vary from one antenna to another. Improving the N term does not often significantly improve your EIRP which contributes to the S term at the other end of the link (assuming two way communications).

Here is an application of NFM to plot the pattern of a 1296MHz dish using sun noise:
http://www.vk1od.net/nfm/applications/AntennaPatternFromSun.htm .

Presumably, you'll need some sort of RF front end to translate your
desired RF band of interest down, but after that, there's a fair number
of spectroscope/spectrogram programs out there..

I like DL4YHF's spectrum lab:

http://freenet-homepage.de/dl4yhf/spectra1.html

He's got a beacon logger setup for it, that you could probably modify.

What you are looking for is generally called semi-rigid coax. There are 3 relatively common sizes (outside diameter): 0.141", 0.085" or 0.086", and 0.047", as well as other sizes.

There's a lot of different dielectrics and metals available, other than the usual PTFE and copper. For instance, foamed PTFE for low loss, a sort of sintered silica, etc. Silver plated stainless steel is used in cryogenic applications. Aluminum is used in weight sensitive applications.

Vendors are companies like MicroCoax, Haverhill, UniformTube, etc.

googling semirigid coax turns up a lot of hits.

Can the sun really do anything that isnt 'normal' ?
It is man-kinds stunted view of what normal should be that is abnormal.

The sun is not adhering to our predictions based on previous observations.
Bad, bad sun. No cookie for you.

I don't believe anyone will do a thing, until:

1) We can no longer breath the air with out pain and all the birds are gone.

2) The coral reefs, and there for the fish, are dead (salmon are already
going that way.)

3) Ocean acidification has destroyed all oyster, clams, crabs, shrimp,
abalone, lobster, etc... (it is beginning now.)

4) Etc., etc., etc. ...

I would like to think different, but nothing has changed ... Rome burns
while Nero fiddles ... no, greed, corruption and lack of vision will
lead us where it always has ...

Just to clarify, I would use the HF receiver I already have, turn off
the AGC and then process the audio signal. The strength of the audio
signal would be proportional to the strength of the RF signal, and if
I can subract the noise level from the signal+noise level, I would
believe I should have a fair indication of the RF signal strength, at
least for comparison purposes.

Correction, it is actually a plot of the pattern at 2304MHz.

Fine Walter. Urge people not to make one based on your professional
experience.
With Richards pile of books on which to stand you can make a mighty
strong case
based on the antennas you have personally built. Experts said the
same about the
Rhode Island antenna but the ham in the street seems to be happy with
it.!
Ofcourse you can show your academic ability in telling the group WHY
it "cannot possibly work:"
or wait for another expert to state ":why" to save face. Both of you
state it can't work, won't work
or the whole thing is a myth. Don't you feel you owe the group a
professional explanation on which you are basing your findings?
And I don't mean because YOU said it but on the basis of mathematics
or something of similar kind. After all this time I have
been studying this thing I could still be in error and I would welcome
a professional expose if it would save trouble for the posters
and where I can sincerely apologise for my aproach to this antenna
which nobody has faulted with explanation as yet.
Is this "don't make it guys" a pure professional aproach designed to
save your fellow friends from harm
or is it an emotional thing that you are pushing in response to you
book writings being dissed? I presented a series of graphs that I
measured with this antenna on
unwinantennas.com

so you could comment about that even tho you may have been looking for other information that was not there.You could also state to the many naysayers
why you ,as a professional and a judge ,why it reflect a dummy load and the implication of the oscillations. All these would earn you respect that could overcome your anger at somebody daring to question your writings in public and certainly would do something to negate your present passion for hate.
Can you do that for your fellow hams or is there some delight in seeing them struggle and spend while you are laughing at alll. Be a real ham and help your fellow hams after all the hobby is more than making money from them. As far as only Richard being academic I would remind you he is only quoting from books all of which do not address this design so his comments are speculative to say the least where he does not share the professional underpinnings of his speculations given with a sneer.

Art, I have never said your antennas don't work, and I have not seen your graphs. In fact I've never commented one way of the other concerning your antennas. I did make one negative comment concerning your dialogs with the others, but I have not commented on the content of your rhetoric. Furthermore, I was not privy to any of the Dr. Davis posts, even though you have accused me of siding against him. If you doubt this just go back and check the various posts around the era when Dr. Davis is said to have posted and you'll not find any of my posts concerning him or the discussions concerning him.

And you have mistaken one Richard for the other. Richard C is the one who began the comedy in this thread, while Richard H is the one who posted academically. Are you aware of these two distinguished posters on this thread?

Walt, W2DU

Are you saying that one of the Richards is responsible for the '
comedy that you are enjoying and not me? Then you should have the
courage to say so.
Richard C I know can stand on his own feet and respond rather than you
hiding behind ambiguety.
At the same time I do not remember the two Richards having a discourse
with each other on my antenna which if
so you could have made your statement more deffinitive.! Frankly your
response does not ring true and I certainly would not wish you to
continue with your anger against him. But again you are intent on

letting somebody know of your contempt because you haven't fully
vented your anger.
I suggest you put this sort of verbage to one side and view tomorrow
as a new day

Hmmm,

If all would peruse the original post for this thread, its contents are solely derived from the original descriptions made by the authur. The analysis of Weak Force conforms to the original descriptions of the authur. The outcome of Weak Force is confirmed in ALL signal strength reports of at least -40dB. All-in-all, nothing has been denied, negated, nor diminished (except signal strength in comparison to a standard dipole); and all accounts conform to every original postulate offered by the authur. Any consequences of optimizing for neutron emission and maximization for Weak Force are perhaps not notably useful, but might interest those who demand QRP operation from their investments in linears and exotic antennas in the examination of sub-atomic particle physics.

If any comedy has been observed, inferred, suggested, or implied; then its source lies wholly with the readers' misinterpretations with the authur of this new antenna as this thread has been solely devoted to affirming every proposition of this novel antenna degrading signal to observe these nuclear forces.

The variometer is complete and I made a mat form of antenna 24" by 6"
by 1/8
When testing the two at 2MHz the resonant point was passed to quickly
for me to stop the variometer turning.!
This suggests I have too many windings so some will have to be shorted
by the user as he feels necessary.since he probably has more expertise
in that area
Monday I will complete a whip form of same so it can be tried in a
mobile so everything will be shipped by Tuesday
and we can all sit and wait for comformation of all your dire
predictions to see which person hit it on the nose
and I have to crawl on my knees and apologize for my stubborness for
disregarding the plentiful advise given over the years by the experts.
While you are waiting I suggest that you review the law of statics and
instead of looking at
just Maxwell look at what the other constituent providers had to say
and how it compares to Gauss's law of statics.
Googling allowed.

Art, I'm not angry with anyone. What gave you that notion? I have not indicated an anger, nor have I had any intent of letting anyone know of any contempt (because I have none) or that I haven't fully vented my anger. What anger? Where is this coming from? Certainly not from me. If you're addressing me with such outrageous concerns you are either mistaking me for someone else, or else you must have too many Gaussians between your ears that have addalpated your brain cells.

Concerning the two Richards, check the recent posts on this thread.

Walt, W2DU

As I said I assumed that your hillarity was over my antenna. You
certainly did not make it clear
it was the other Richard. Maybe I am getting to sensitive to attacks
and thus showing I still have possesion of some testerone.
Apparently this time I can relax as I am not the one in the barrel tho
that is not a good thing to say.
Have a good week end

Ok Walter I have now read RCs post, I don't normally read his posts
But I don't find his comment hillarious. I never mentioned Neutrons
or zip cord
and his use of zip cord does not show any evidence of the wires
crossing each other from one coil to another
so he is imposing a lumped load which is opposite to the intent of the
design! Then he stated he had achieved equilibriumwhat ever that word
means to him
All in all it just doesn't make sense to me as always. I rarely can

figure out what RC is trying to say
since he mixes truth with lies as with a Shakesperien play, which is
why I do not read him and thus hillarity has escaped me.
I certainly have no idea what Franks response to RCs post signifies
either
What a mess occurs when one solely tries to deceive!
I am ready for a couple of quiet days out of town despite the cost of
Gauss

No one is saving face or conspiring against a new idea. You can`t break the laws of physics no matter how hard you try.

Antenna performance is based on lengths of wire in the air and the currents in them. Take a broadside array for example. It is usual to drive current through all the elements of a plane in the same phase so that the fields at a distant point perpendicular to the plane of the array are additive to make a large signal. It is a matter of radiator lengths and currents.

Now consider a small diameter coil as a radiator. It is called an radial mode helix because radiation is radial (perpendicular to the axis of the coil). It has two extremes. If collapsed, the coil becomes a single loop. If stretched to its maximum, the coil becomes a straight wire. If controlled so that the same magnitude and direction of current flows in all configurations, the straight-wire version of this coil should produce the greatest radiated field strength perpendicular to the coil axis in the far field.

Best regards, Richard Harrison, KB5WZI

Yanno, I just don't get it ...

In looking back, over decades, I see that I, most likely, learned more from antennas I have built which didn't work, than the ones I built which worked extremely well ... sounds stupid on the surface, I know--but, none the less, true.

There is a thread running now on the lazy h antenna--never one of my favorites. But hey, look what the guy is learning that started that thread! And, he seems determined, if it is a great antenna--he'll know by the time he is done!

Many of my mistakes were in my own construction(s.) A wire crossed to the wrong point--miscalculation of lengths/inductances/capacitances/etc. Sometimes I had built and written off an antenna, only to look, at some later date, at one someone else had built (and which functioned well) to see my mistake(s.) Sometimes the antennas just didn't work as expected, and they never were going to; and, even if I came across someone claiming they had one "working", and I examined it closely, while under use--I might see they only wished it to work well. Were they "wrong?", well, yes and no ... obviously they were chatting someone up!

Remove all the fun from amateur radio and you are just left with a bunch of angry "Brass Bangers!" Or, forever boy scouts at a contest ... :-)

Regards,
JS

We do not possess an all powerful one world government, John. How else could
anything be done?

If we continue on our present path, there is a chance that billions of
people and other species could die as a consequence.

The sad truth is that if there was one world government that was all
powerful, the only way it could reduce the strain on the world's ecosystem
is to kill billions of people. Gee, that sounds familiar, doesn't it?

It is easy to say "do something". But when asked precisely what and by whom,
things fall apart in a hurry.

Anything that could be done, will affect people, their economies, their futures, their children, etc. Who is going to voluntarily put a gun to their head and eliminate themselves from the true problem being experienced by the Earth?

Ed Cregger

<ArthurUnwin@gmail.com> wrote:

>I never mentioned Neutrons

You can't spell is why (neutrino).

It still amounts to the same thing: an antenna designed to suppress
the signal to optimize sub-atomic particles with their weak force.

Further modeling has borne out how weak: varying between the -30s dB
and -40s dB.

No other data has been submitted to contradict what has been witnessed
for three centuries by millions of operators. As I have offered
throughout this thread: proof positive that an antenna optimized for
the equilibrium of the Weak Force must suppress signal to qualify.

By the authur's intent, design, construction details, expressed logic,
and demonstration through models and in dependant testing, that
suppression has left only a Weak Force. Further improvement in
modeling and construction may yet achieve -60dB levels of signal
degradation to achieve a superior Weak Force antenna example.

This is truly deserving of a patent - except that the PTO mandates it
must have some commercial gain. Can one express it as -60dB$?

Would you be able to find a coin that small struck at the Denver Mint?
The tax mil would only be -30dB$. Would one need a 1000 bay
unwinantenna to equal on mil of monetary gain? What would its carbon
footprint be when a Henry fed it?

Ah, the infinite intrigue of Weak Force Antennas (hope the authur
realizes this may lead to a trademark infringement).

Micro Coax (http://www.micro-coax.com/) is one source for semi-rigid coaxial cable, and comes in (IIRC) up to 8' lengths. The stuff isn't cheap, though... be prepared to empty your wallet!

Sorry for the delay in answering back. Trouble with the computer. All fixed
now.

Ok on the length of coax. I have left it at 100 feet for now, so if I do
decide to higher the antenna in the future I can do.

I have a trapped centre feed dipole up for 80 and 40 meters.
The centre of the coax is connected to the half that points to north and the
braid is connected to the one that is pointing south.

I feel a bit daft asking this, but how can I tell if the antenna is running
north to south or south to north?

Absolutely not ...

"They" have simply designed the world wrong. We need our jobs closer to
our homes. We need small manufacturing plants close to cities, and of
varying products so as supply the most needs of the city as possible.
Mass transportation in place of single cars ... etc, etc ...

We need to manufacture "things" to last a lifetime or two, and out of
metal, wood and glass--instead of cheap plastic poisons to fill our
dumps, streams and oceans with ...

Etc, etc, etc ...

Oh no, it is all easily "fixable", it just won't be done--greed and
corruption take a far different path--one which always ends in the end
of the particular civilization in question ... look at the cheap plastic
"toy" radios we have today--a sharp contrast to the sturdy metal/glass
cases of yesteryear ...

Those who know NOT their history are doomed to repeat that history ...
today they "rewrite history" in the image "they" wish ...

Regards,
JS

Good use? There is every indication that Arthur has never made use of a spell checker in any post he has made. Couple that fact with his peculiar antenna theory and you end up with mostly gibberish. Arthur has, on a number of occasions, tried to lambaste the American educational system. At the same time, he provides ample evidence that he was short-sheeted during his education abroad.

> I just realized this would be yet another trivial thing which would
> "fool you" once again ...

I wasn't fooled in the least, "John". I recognized an incorrect word at once. I even provided a definition of the word used by Art. The fellow who was fooled provided numerous definitions of a word not used. That'd be the anonymous "John Smith".

I don't know where you get this straight busines from. the wire will
radiate
no matter what shape as long as it is in equilibrium which means
straight or otherwise.
No law says it must be straight or else unless you can show it to me.
The helix is not straight! Making a helix a full wave circuit gets rid
of the counterpoise,
it does not stop radiation. Kraus suggests that a helix can supply a
16 db gain which is very high
but tnever the less gain can be achieved. So I do not see the point
that you are silently dwelling aponto justufy that it can,t work as
well as
radiators MUSt be at right angles to the earths surface for maximum
vertical gain. You have never explained the u nderpinnings of your
statements in academic form without which there is nothing I can

debate with you

The idea was to model your antenna. The code is there for anyone to
verify in case I have made an error. The model results, including
input impedance, and gain, are shown below the code listing.
The GH card is in NEC 4 format. All other cards conform to
NEC 2.

My program is not Nec based so I am not familiar with that routine.,
I cant model my antenna because of the pre twisted wires. I can
however
model a combination of two helix antennas without interweaving into
one circuit.
where one helix antenna is slightly larger diameter than the other
My program shows instances of gain! So the question becomes is your
model
based on zip cord which is suggested by one and secondly what was the
reason for the combimation of two antennas
to shrivle away into dust or the equivalent of a dummy load. It is
also suggested that antennas such as this
are breaking the laws of nature so does your program show the arrival
of doom ?.
I am making this antenna very frequently and all these things
predicted are just not happening. But then I would never use
zip cord or violate the rules of nature if I was advised which one I
was violating but apparently that is a secret.
So Frank what is the antenna configuration etc that your program
represents so that I can understand the particulars that you have so
genouresly probided so all may share

It is incredible , how silly and wrong the comments here are.
- All facts are disregarded and so many wrong things are
told, that I think, you all better remain with your wire antennas
as has been since 100 years ... and you better believe
that the world is flat and that an airplane never can fly,
as scientists teached some time ago ...
Maybe you will understand when the time is ready for that ...
-
I just tell you, that you can read the real facts here:
http://home.datacomm.ch/hb9abx/ant--abx-e.htm
and
if someone wants to know the contract, he has to sign
before obtaining the plans: Send me an email
and you will get all conditions - nothing is kept secret
as Buck wrote. Probably his mail was lost in the
Internet, and that is not my responsibility. Sorry.
With kind regards: Felix - HB9ABX

Correct Please point to the particular law that I am breaking, that
would really help out a lot
>
> Antenna performance is based on lengths of wire in the air and the
> currents in them.
By performance you meam energy in vesus radiation out
as with a closed arbitary border.

Take a broadside array for example. It is usual to
> drive current through all the elements of a plane in the same phase so
> that the fields at a distant point perpendicular to the plane of the
> array are additive to make a large signal. It is a matter of radiator
> lengths and currents.
That is for a radiator based around intercoupling of radiators not one
based on radiation per unit length of radiator
The "large" signal is a resuly of how the radiation is arranged. It
does not create extra radiation it just removes radiation fro one
arear
to supplement radiation in other areas. It does not create more
radiation per radiator unit length
>
> Now consider a small diameter coil as a radiator.
A loop radiator or did you mean a coil?

It is called an radial
> mode helix because radiation is radial (perpendicular to the axis of the
> coil).
No. That is definitely not true!

It has two extremes. If collapsed, the coil becomes a single
> loop.
Wire stays the same length ala apples with apples

If stretched to its maximum, the coil becomes a straight wire.

Ok. still the same amount of wire

If
> controlled so that the same magnitude and direction of current flows in
> all configurations, the straight-wire version of this coil should
> produce the greatest radiated field strength perpendicular to the coil
> axis in the far field.

This doesn't radiate more per unit energy supplied. Ther is no total
increase of radiation per energy put in.

Hmm so now you are moving away from total radiation to a robbing Peter
to pay Paul situation
So your radiator is very lossy as much as it has gain, which adds up
to total radiation
per unit length

You forgot to make your point. My antenna with the same wire length
has the same radiation as yours does per unit length of radiator
so in your casev some how the ratio root LC became smaller while the
wire stayed the same lengthj!
How did that happen?

You are saying that a straight radiator produces more radiation per
unit length than any other antenna that does not have a straight
position such that the radiation per unit length reduces the
efficiency of the radiator the ability of producing radiation.

So this is where we part

since for a given length in equilibrium root LC is always the same
thus so is the radiation. Is this a law that I am violating?

What does the law state?

RH this is my last shot of trying to analyse what you are saying that
leads to the demise of my antenna.
Now be specific for once and respond to each which I have high ligted.
And as a final comment describe how one helix antenna radiates more
than two helix anteena made of opposite polarisation because you
continue to suggest this despite the fact we have doubled the wire!.
Let us come to finality with respect to what you have been pushing for
the last decade,

P.S I am in St Louis for a get away and it is to hot and humid to go
out. Makes sense?

>

Why do we always mount our HF Yagi's in the horizontal plane?
Antenna maintenance would be much easier for those of us with tilt
over towers if the antenna were in the horizontal plane when down for
maintenance!

John Ferrell W8CCW

John, A local guy has his yagi hinged at the top where the downward
pole slips
into a "U " shaped clasp. a
As his foldover comes down the leverage supplied by
the yagi removes the pole from the clasp and the yagi arrives at
ground level in a horizontal position

As alway, I remain open to embrace any new
designs/techniques/construction-methods/plans/breakthroughs/etc.

After building/using "it" (your antenna in question) I went back to the
DLM. Granted, I have not figured out how to make a true multi-band
version of the DLM, yet, no problem; I have never been fond of the
"one-size-fits-all" antenna, anyway.

I would encourage other to give it a go--I am not infallible and may
have sloppy or inadequate means to realize the full potential ... I have
made plenty such errors in the past ... :-(

Choice is nice!

Regards,
JS

Has it ever occurred to those involved in this thread that Art has outsmarted us all, and that he is simply pulling our legs and we fell for it all the way? I know some Brits who are pretty smart blokes, but would like to make us look like idiots. Some of them can't even get over their loss in the late 1700's.

Walt, W2DU

I was thinking the same thing the other day when I read part #1 of
the Art papers..
My first thought was sheesh, there is no way anyone could be "this"
crazy... This must be a troll of epic proportions, and we all are
taking
the bait, hook , line , and gaussian sinker.

vertical yagi's work fine... if you can get them far enough away from the conductive tower and mast either vertically or horizontally... though i do believe you get better ground reflection from the horizontal polarization. There is a new product that allows yagis mounted horizontally to automatically pivot as you tilt over a tower so they stay level with the ground.

in A0 51 antenna
http://xe1mex.gq.nu/antenas/yagi.html the original design is basic.
would I like to learn about antenna and put the actual antenna into
mmana-gal.

I have built the antenna but I want to fine tune the antenna with mmana-gal
so I understand more about how these term " good reception", "good
signalling... good connection " really mean in the design.

how to fit in reflector, driven, direction 1... direction N?

first time to mmana-gal would you please guide me a little bit.

As soon as I get an opportunity I will rotate mine to vertical at
least until I can investigate the possibilities. If you can recall
more details of the new product I am interested.
The scheme offered by Art sounds like my best bet so far.

In the past I have worked from a step ladder with the tower lowered
and tilted as far as possible. I did not forsee that two knee joint
replacements would take away my use of stepladders for a while!

John Smith wrote:
"There is a thread runnung now on the lazy H antenna--never one of my favorites.:

Yes. I believe it started with the question: "Has anyone ever actually built a Lazy H for 10 or 11 meters?"

Although I`ve built many antennas for 33 MHz, a frequency assigned to a company I worked for over a long period of time, none of those were Lazy H`s. I have built many Lazy H`s for several other frequency bands used for shortwave broadcasting but 10 and 11 meters are not assigned to broadcasting. The Lazy H, with a plane of phased resonant reflectors directly behind to make the array unidtrectional, is one of the most popular for shortwave broadcasting. The highest frequency band I`ve used is the 17 MHz band. Nothing significant will happen if the same 17 MHz antenna is scaled for 29 MHz. In fact our shortwave antennas were physically modeled at 450 MHz, before the first full-sized shortwave antenna was ever built, just to prove the design. Measurements on big and little antennas proved both to give the same results.

I`m inclined to believe the questioner made some mistake and there is nothing wrong with a properly designed and constructed Lazy-H antenna on any frequency.

Best regards, Richard Harrison, KB5WZI

No.

Look at the horizontal and vertical diagrams of a Yagi.
(Talking about a single Yagi, not stacked)

The narrowing of the beam characteristic is only dominant
in the horizontal orientation, the vertical retains about the
characteristic of a single dipole.

So if you tilt a yagi to vertical, it will receive from all
directions, especially the EMF noise in your vicinity.

When horizontally mounted, it will receive of course from
above (the sky) and from the bottom below your tower
but generally there is less interference than in the whole
360 degrees around you.

Repeat: the vertical yagi diagram is not much better than
that of a single dipole, regardless how many horizontal elements
you add in length of the beam. Try it out of you don't believe,
but listen to the noise you get, not the signals.
Only stacking of yagis can improve the situation.

w.

That proposition is not born out my models or measurements of real antennas.

It is true that the E plane and H plane half power beamwidths are different, but as boom length (gain) is increased, the two approach each other.

Owen

385. Re: Vertical Yagi?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-13 07:59:30 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <A8WdnYZttNx5KOTVnZ2dnUVZ_oTinZ2d@posted.easystreetonline>
Source record: 24159

One of the advantages of a Yagi is its directivity. When mounted horizontally, its horizontal pattern is quite directional, but the pattern in the vertical plane is relatively broad -- the vertical pattern of a typical HF Yagi in the forward direction, in fact, isn't much different from a single dipole. If you mount the Yagi vertically, the two patterns swap so the horizontal pattern ends up very much broader than when mounted vertically.

A vertically mounted Yagi is vertically polarized, and vertically polarized radiation reacts differently with the ground than horizontally polarized radiation. So rotating a moderately or very high yagi from horizontal to vertical will result in loss of low angle radiation unless your ground is very highly conductive.

These effects can be very easily be seen by modeling.

Roy Lewallen, W7EL

> Unwinantennas.com/

Suddenly, here's just a TON of stuff that needs some good sense sprinkled on
it. Just a few highlights:

I just took another look at the website and further examined the graphs at
the bottom. Per your instructions, using approximately 2000 ft of wire
means the antenna is wound for a wl of 1000 ft, 305 meters or around 1 MHz.
How is it you're getting a decent SWR nearly everywhere from 1.0 to 100 MHz?
Look, the WORST number for SWR is about 4:1, well within the range of any
decent tuner. BTW, it looks like the response of a comb filter, except
that the cancellation frequencies between the reinforcements don't look as
lossy as they should look.

The variometer will do variable transformer coupling. OK fine, but I think
you should have provided a description for one. The link to
http://www.qsl.net/in3otd/variodes.html was instructive but ... I have no
idea what coil inductances to shoot for. Groping in the dark is not fun.

What does it mean to move the frequency as a multiple of wavelength?

What does it mean for the antenna to vary as I turn the knob on the radio?
I've got decades of experience with this hobby and that does not compute.
You shouldn't throw this stuff out and figure we're mind readers.

160m rotatable antenna? I don't travel in those circles. If that was a joke, I guess I need my sense of humor recalibrated.

Here's my own "tell you what": I'll wind one of these things for 20m, which isn't a lot of wire. I have an antenna analyzer that will tell me a few nice things about what I have.

Then if the SWR is anything like reasonable, it's Kenwood Time! I'll check for who I can hear and try working him. ... and I'll check for WWV on 15. I can usually hear him any day, often on a cheap portable radio with a whip antenna.

Using a local ham (eliminating the bulk of QSB) I can compare antennas for equal S-meter readings with a switchable attenuator in line with the better antenna.

That will settle it for me.

I read somewhere you get more ground gain with horizontal . Something
to do with Brewster angle.

Roy, are you talking about high gain yagis? I just looked at the
beamwidths of an 11 element DL6WU Yagi on 2m and got 35 degrees
horizontal and 39 degrees vertical in EZNEC. Not much difference there.
Alan

I have tried two variants of the model: Interleaved, and one slightly
inside the other. I used uninsulated # 14 AWG copper, and designed for 7
MHz.
The copper conductivity used is 5.8001E7 S/m. At resonance the
the input impedance is 3.1 ohms. The radiation resistance computes
to 0.14E-3 ohms. For 100 W input the total radiated power is
2 mW. At 1000 m, normal to the axis of helices, the field strength
is 3.7E-4 V/m (RMS). I have found, for such closed spaced helical models,
that segmentation is critical. My model uses 2200 segments,
and takes 28 seconds to run. The "Average gain test" returns "Good".
The "Average gain test" is a method employed by Nittany Scientific's
NEC based programs to estimate model validity.

The interleaved model version appears to have a slightly better
performance than the "Coaxial" structure. It is essential,
when testing such a higly compact radiator, that a balun
be used to feed the antenna. The "Tak-tenna", for
example, has a very low radiation efficiency. It is
designed for use witout a balun, and the bulk of the radiation
occurs from currents flowing on the outside of the
coaxial shield.

Thank you for that Frank but something is incorrect sorry to say!
The impedance for a single wavelength of wire was close to a 100 ohms.
When I dampened it by adding wasvelengths to it the impedance
stabalised around 68 ohms.
I do not know what the optimum number of wavelengths should be for the
high band.with respect to gain and impedance
There was a question asked some where with respect to the number of
wavelengths required for optimum
which really I do not know.! What I do know that equilibrium is the
cornerstone so the magnetic field produced
by the radiator must equal that of n times wavelength. The Variometer
either extends the strength of the field
or diminishes it such that it is symptomatic of a wavelength which is
in equilibrium and also resonant. at the particular frequency at hand.
If all is at the above there is never a need for a choke or a balun
since with this radiator you never move away from the resonant point
as with a filter. The on ly imbalance is the coax feed that you are
connecting to a perennial balanced load. I would add that I wind my
antennas with a pretwisted wire whiich basically four coils

-47dB

It will take a whole lot more signal degradation to reach the Weak
Force threshold (about 83dB more, just to compare to the Strong Force
- much less a standard dipole).

Hi Frank,

With the disclaimer:

<ArthurUnwin@gmail.com> wrote:
>My program is not Nec based so I am not familiar with that routine.,

Your results will no doubt be shunned as unauthentic (in spite of his
program being NEC based, but 20+ years older - we won't go into his
confusion of not knowing what NEC is).

I've noticed an old hobby horse trotted out to the starting gate:
On Sat, 12 Jul 2008 12:21:17 -0700 (PDT), Art Unwin
<ArthurUnwin@gmail.com> wrote:
>based on radiation per unit length of radiator

This nostrum was offered years ago to explain "efficiency," and no
doubt the corruption of what "efficiency" means will be used to muddy
the stupendous loss into figures of amazing merit.

It should come as no surprise that even allowing (patronizing the
authur as several contributors here desire) for this aberrant reading
of "efficiency" (per unit length) that the authur's Weak Force Antenna
design is not one ten-thousandth the size of the standard dipole. As
such, this new design is still not as "efficient per unit length" as a
standard dipole when the authur's terms are accepted.

Over the past 38 years, I've had HF yagis... a homebrew 3-el 15m monoband yagi (16' boom) and 3-element triband trap yagis (12' booms) on tiltover masts. I've never encountered maintenance issues with operating them in the horizontal plane. A step lader is all that's needed to reach the driven element, and the antenna can be rotated to reach both parasitic elements.

It seems to me that while Front/Back ratio might be similar, a vertically polarized yagi would have a significantly reduced Front/Side ratio. If operated in the vertical plane, I'm guessing that performance may also be adversely affected by a conductive mast in the near-field. If performance was same/similar and maintenance was much easier, I think you'd see many more vertically polarized HF yagis.

If you n times a wavelength, the armor will become to
heavy to wear. :/

Hate to break this to you but resonance, SWR, match, etc, ad
nausium have nothing at all to do with the presence or lack of
common mode currents on a feedline.

What "facts" have been disregarded?
Don't piss down my back and tell me it's raining..
I have needed test apparatus to be able to tell the difference.
And yes, I'm sure I would be better off sticking with "my"
wire antennas, but that has nothing to do with the issues
at hand. I use only manly full sized antennas designed to
kick butt. It would only be natural that they would be superior
to lesser loaded designs.
Now, don't be confused. I have no real issues with your
antenna. Just the antenna you used as a reference.
I'm sure your antenna is far superior to the Unwin design
which is presently being offered by the wizard of IL.
But don't be confusing yourself that it is equal to a
full size specimen. It's not, and never will be. Ever.

There have been several very credible posts that have convinced me
that I do need to stick with horizontal polarization with the Yagi.

Fortunately, the physical limitation of "no ladders" will go away in a
few months as I continue my recovery from two knee joint replacements.
However, as I get older I may find the limitation returning. I want to
be prepared for that time.

My antenna is modest in that it is only a Cushcraft A3S and I
generally keep the crank up antenna height at about 50 feet. This area
(Greensboro NC) does get an occasional hurricane and some ice storms.
There are times when I would like to reduce my risks on the forecast
weather.

I expect I will pursue a lighter (home brew) version of the Tilt Plate
system.

Currently the coax is fouled at the rotor and I will need outside
assistance to clear the problem. It is not a big issue but I do like
to solve my own problems!

Test Preparation Software

Pass your US FCC ham radio license test with ease. Our test preparation software
serves as a training aid to help amateurs and prospective amateurs pass the VEC's administered test. When you can consistently pass the test given by our test preparation software, you will almost certainly pass an actual test.

Our ham radio license test preparation software uses the latest officially released VEC's approved question pools. The program breaks the test into different sub-element. Integrated into the software are illustrations and Part 97 rules pertaining to the current question. The program tracks the progress of the tests taken. Once you have mastered each sub-element you are ready for the official test.

Visit our web site at http://www.hamradiolicense.net for more information.

403. ART'S ANTENNA

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-13 20:48:52 UTC
From: derek <derekbluey@gmail.com>
Message-ID: <6049895a-5bd2-4a25-8f01-8bd39246e905@z66g2000hsc.googlegroups.com>
Source record: 24177

Met an old ham a couple of weeks ago he had recently moved into a senior citizens complex and was unable to have antennas of any sort erected, all he had was, as he put it, a piece of wire in the loft. After a bit of thought I decided to make one of Art's antennas for him. I made a former 16" long by 10.5"diameter and contra-wound aprox 550' of twisted (1100' single) 19 gauge copper magnet wire onto it, covered same in pvc tape and took it over to him yesterday morning, he took some swr readings they were as follows.

SWR
1.8 = 1.2 :1
3.75 = 1 :1
7.075 = 1.7 :1
14.075 = 4 :1
21.075 = 6 :1

He did not have a variometer but is going to build one, will post results when He gives them to me, I left him playing with the antenna and he seemed to be a very happy man.

Derek

By the way, I was just into Lowes hardware store this day. I was in search of some "Sono Tube" or "Quick Tube." It is a cardboard tube, very sturdy. They had lengths of ~4-6 ft. The largest diameter they had was 12" (they had 8,10,12 inch dia. in stock.) I needed 18" or larger as I was going to use it for construction of a "cat tree."

But, anyway, sounds like excellent material for a "former."

hi

i was just wondering once nyc hits the deadline to switch
broadcasting to digital if the channals we use now

2-13vhf would continue specifically would other channals in
that range be avail like say ch6

or will it just be say one or more digital channals stuffed into
the same space now occupied by ch2 for example depending on how cbs
wants to do it

also here uhf 14-> had really only a few channels that were
broadcasting should we expect many new channels to be
broadcating in that range or just mostly same

wondering if were going to see a shift of the primary channels
here being more 14->> vs the current heavy use of 2-13

reason being most have antennas that are really for 2-13 and
alot are wondering if the uhf is going to be hot they will obv
need to add new antennas

thanks

Good on you Derek. It would appear the instructions on my page
worked out OK for you.
Can you give details about the former you made and what was the length
of the turnings?
If you like I can send details on how to make the variometer and it
wouldn't surprise me if tha
local club doesn't ask you for a demonstration how to make one.
You have no idea how happy you made that ham since he can now work
anywhere
he wants to as well as the local repeaters I garantee he was not a
happy man in the old peoples home
and having the ability of just a piece of wire
Cheers
Art

Not sure what to say. I have designed some ultra compact vehicular helices for 0.54 to 210 MHz. Network analyzer measurements indicated the models as very close to that predicted by NEC2.

The project was abandoned due to very poor results -- even with a 30 dB pre-amp the reception was unsatisfactory. The auto manufacturers are desperate to have a vehicular BC/FM/Digital antenna that fits into a "Sharkfin" shaped radome.

Heck, I may have to build one of Art's models and measure the parameters.

73,

Frank

Obviously Frank I do not have your experience and for many years total opinioni. I feel comfortable about most things is that it will never work or it is a dummy load e.t.c.
I have never tested it for gain or anything like that as those sort of things arouse the ire of hams more than anything.
One thing I am absoluetly positive is that I have made many antennas of this design over the years and the measurementsmade on the SWR meter in Aussi land is pretty much the same impedance that I get with my MFJ 259 b. If I could model the antenna with interleaving then I would have some idea with respect to testing. When I place a helix over a helix of the standard design pre provided as an example I also get similar impedances to what I measure
so it is the pre twisted wire and the fact that it then becomes four interwound helixes is what makes the difference. When I have finished my present work I am going to think things out all again or wait for the others who are making them to present some observations. My flat matt antenna seems like a good candidate for the shark fin arrangement and that is one of them that I am sending to California! So for this summer I will have to endure the continueing caustic comments of the group who may well finish up on the correct side since they are obviously in the majority. For me the only thing that needs to be completed is a chamber test and Illinois University has one of these so.....By the way Frank the antenna did quit well on a quick sorty thru the TV channels where I anticipated just snow but I didn't get to deep on that as I vie2wed it as novelty for if I want to mess with 2.4 Ghz

> Alan
>

No, I'm not. The OP specified HF, so I'm talking about Yagis of up to 5 or 6 elements or so. Ones with a larger number of elements would significantly narrow the pattern in both planes. I'm surprised that the beamwidths approach about the same value, but I haven't done much modeling or any measurement of Yagis with a large number of elements, so I'll believe it.

You know Frank, there is always the possibility that what I have is in
fact a induction
heater without radiation shielding. In other words the copper actually
radiates a larger portion of energy into heat
if there is a ferro magnetic material with in the near field! So a
heat test is required on the antenna in a field where
there is no possibility of induction heating. Thinking out loud here
as I have not read up on the subject of induction heating
which I thought was a result of hysterysis of ferro magnetic materials
where I am using a diamagnetic material. There maybe a spill over of
sciences here

Another good use for those concrete form tubes is making antenna carriers.
Made one for a three element yagi, A3S, and it works fine.
Put a couple of tubes together so it was just over 14 feet long.
Added two garage door "D" handles, put a plug in one permanently and a
removable plug, held in place with Velcro in the other.
Now for Field Day or SkyWarn Recognition Day we can just pick it up, put it
on the trailer, hold it down with a couple of tarp straps and drive off.
Very easy to get the antenna in and out of the tube.
Protects the antenna and makes transport a snap.
All elements are left at their fully assembled length, no break down
required.
With a 10" inch or larger tube the fiberglass mounting tube for the driven
element does not even need to be removed.

You may also wish to try WSPR which is very useful for antenna
comparisons on both TX and RX by other stations running the software
and reporting.

It is entirely possible that it is simply conduction heating with
derek's 8 Ohms of wire resistance where yours is going on 17 Ohms of
wire resistance at a minimum:

The following explains the construction:

http://www.g0mrf.freeserve.co.uk/variometer.htm

Variometers can be very lossy variable inductors. For proper
matching 2 elements are required.

up that is similar to mine except I split the coilnumbers by two and
it is still to insensitive so now I have to put a blob of solder in
betwwee the coils to short them until I get the right ratio to suit
the antenna. I like to slow down the swr meter so that I constantly do
not scoot pass the right point

That one is at least four times the coil turns needed. The previous
one was at least two times the number of coils need.
And if the wire length used was 1100 feet or so the latter also is
much more than required and can be divided by two again.
The idea is not to put a 1000 feet of wire on the variometer or to use
the radiator beyond the HF bands!

A general rule of thumb for electrically small antennas is: small-broadband-efficient, pick any two. One of the common features of many small antennas is some lossy component or components which make the bandwidth acceptable. Of course, this also means lowered efficiency, often to an extreme extent. But most amateurs are able to measure SWR and almost none are able to measure efficiency, so the loss fools a lot of people into thinking the small antenna is performing well. I suspect the variometer is the "secret ingredient" in this case, and that its chief function is to provide loss. People duplicating the antenna might try substituting a non-inductive resistor as a simpler way to achieve the same result.

This isn't to say that a small inefficient antenna "doesn't work". I've personally worked over 30 countries with a watt and a half on 40 meters using simple antennas, and many, many people have done a great deal better with much lower power. So you can still work a lot of stations with a 100 watt rig and 1% efficient antenna.

You can get it in longer lengths (at least 100') in a big coil (it's
like copper tubing, after all).

The stuff isn't cheap,
> though... be prepared to empty your wallet!

Depends on what you call expensive.. $4-10/ft in 50' coils is a typical
price. Pasternack sells 5' lengths of 0.085" copper for $3.66/ft

I think he's talking about lower gain (e.g. a 3 element beam for 20m), where the 3dB beamwidth might be about 50-60 degrees in the Eplane (parallel to the elements) and 80 degrees in the H plane (perpendicular to the elements). The 80 is about the same as the 3dB beamwidth of a dipole.

For higher gain antennas (e.g. your VHF/UHF), the beamwidths will be pretty close in E and H planes. (since a larger fraction of the overall antenna gain comes from "array pattern" gain rather than the individual "element patterns")

Of course, the polarization sensitivity of the ground reflection makes the horizontal antenna usually a winner overall.

> I'll believe it.

Here's a sort of intuitive approach to the conceptual analysis...

Consider the overall pattern to be like that of a phased array where you multiply the pattern of an individual element by the pattern of the array assuming that the elements were isotropic. Indeed, in a Yagi, not all the elements are excited equally, but bear with me..

So, in a 3 element antenna with a gain of, say, 5dBi, you're getting about 2 dBi of gain from just the dipoles, and 3dBi of gain from the fact that you've got 3 elements in an array. The beamwidth is going to be a combination of the array pattern (which is the same in vertical and horizontal planes) and the element pattern (which is not)..

In a higher gain antenna (say 12dbi), you've got the same element gain 2dBi) but the array pattern gain is now 10dBi, so the shape of the latter will dominate.

Who knows absolutely?

But, most likely, he means a dipole.

On a full wave monopole with no counterpoise and choking off the outer braid ... I guess you have "one element" as opposed to "2 elements" (for example: monopole-with-counterpoise/dipole 1/4 wave, 1/2 wave.)

But then, I am guessing. <scratches head>

In most cases an inductor, and capacitor, is required to match
a complex impedance, as follows:

Shunt C, Series L;
Shunt L, Series C;
Series L, Shunt C, or;
Series C, Shunt L.

Only rarely can a single component provide a match.

73,

Frank

There ya' go ... his response.

It appears, what he was saying was/is, you cannot obtain maximum transfer of power to the antenna with the variometer alone--you must use a pi/LC/etc. (a capacitance in conjunction with an inductance) ...

I re-read his post, that meaning was implied well--but I could only see it with hindsight.

No. A variometer is simply a variable inductor.

I should also have added to the above:
Series L, Shunt L etc. etc.......

Then what I can do is to split the circuit in half of a varometer
and connect one in series with the positive and one in series to the
negative
so I have equal turns added or subtracted of opposite wound and
controlled by the single motor.
Sounds good

437. AM Loop Antenna Design

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-15 06:05:06 UTC
From: Bill B <wrongaddress@att.net>
Message-ID: <f565a299-ffe7-4488-a751-1efedda7ce50@s50g2000hsb.googlegroups.com>
Source record: 24109

I made a 15 inch square (broadcast band) loop antenna using 2 crossed pieces of wood and about 14 turns of number 18 copper wire. I added spreaders in the center sections to increase the spacing between the windings and reduce the distributed capacitance. Works well and has a Q factor of 100 or more at 600 KHz. I get about 800mV from a local 50KW station.

But the wire is concentrated around the outside perimeter of the loop and I'm wondering if there is an advantage in winding the loop so that the wire occupies more of the interior space. This would require a longer winding to maintain the same inductance and would further reduce the distributed capacitance, but would also increase the total resistance somewhat. Seems like a longer winding in the same space would produce a larger voltage, but at the expense of some additional resistance which may degenerate it somewhat.

What would be the optimum given a 15X15 inch square space?

-Bill

Other combinations can be used, for example, adjusting a transmission line stub length and position, or a transformer in conjunction with a reactance. The point is that an impedance has two values, commonly expressed as R and X or as a magnitude and phase angle, so to achieve a specific impedance requires two "degrees of freedom" -- that is, two things which you can adjust and which, in simple terms, don't adjust exactly the same thing. With only one adjustable element, you can get a specific R, say, or X, but not both.

This is exactly what you want:
http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-08-72A2.pdf . It's

alphabetical by state, so scroll down to NYC on page 34.

Yes, the action on UHF will be hot, since Channels 2 - 6 are not great for digital TV signals and are being avoided.

Also, please note the existence of newsgroup alt.video.digital-tv which is much more on-point for your question.

BTW, newsgroups are not for text-messages. Using punctuation and capital letters makes it easier to read your questions. Thanks. (Or maybe tks ;-)

Did you feed it with 450 ohm ladder lien all the way back to the
tuner, or did you use some type of matching network?

With only one adjustable element, i.e. ladder-line length,
I get X=0 and 35 < R < 85 ohms which is close enough to
50 ohms for most of us non-perfectionists.

No big deal, but we should keep in mind he may be using his cell phone
to access USENET/internet ... I have done so one mine, but the darn
screen on the phone is so small--well, and my eyes so bad, I gave it
up--but, creating capitals on a cell phone is difficult/slow enough that
one soon abandons any attempt ...

These REALLY Improve mobile antenna transmission by making your antenna an actual ground plane!

Fits at the bottom of standard 3/8" stud mount antennas

http://cgi.ebay.com/Mobile-Antenna-Reflective-GROUND-PLANE-Cb-ham-radio_W0QQitemZ280244585044QQcmdZViewItem?hash=item280244585044&_trksid=p3286.m14.l1318

Optimum is wire around the outside. You want to capture as much of the field as you reasonably can. Imagine it this way: if you have a 15x15 loop and put say a 5x5 loop inside it, co-axial with it, and put the two in series, you get the sum of the two. But what is the performance of a 5x5 loop relative to that of a 15x15 loop (given that both are much smaller than a wavelength)? There's still some question about the optimum arrangement of the wire around the outside, though. The largest area (the largest total field flux) enclosed by a fixed length perimeter would be where the perimeter is a circle, so there's some advantage of making the loop more circular. It's not terribly likely you'll notice much difference from your square, though. But you might find it useful to download one of Reg Edwards' legacies, RJELOOP3.EXE, "Multi-turn, square, frame (or loop), receiving aerials." It will let you play with different wire sizes, numbers of turns and wire spacings, and give you a good approximation of the expected Q, equivalent shunt capacitance and efficiency.

Small loops at low frequencies can be useful at rejecting locally generated noise from things like electric motors or even microprocessors, because that near-field noise tends to be predominantly electric field which is vertically polarized, but to do that well, the loop must be symmetrical about a vertical axis.

Cheers,
Tom

Not sure I understand what you mean. Comments by Roy, and
others, noted. All these methods are certainly valid. The first step is to
determine the actual impedance of your load before you attempt
to match it, and then design an appropriate network.
For measurement a vector network analyzer is the best method,
but expensive. The "TAPR" analyzer, by Tentec looks
good at $655. Most of the cheap analyzers are not very
accurate, and VSWR is not very useful.

The Smith Chart; provided by Dellsperger, at:
http://www.fritz.dellsperger.net/ is an excellent (free) tool for
matching network design. Also Chris Bowick's
"RF Circuit Design" (At Amazon.com) provides an
insight in the use of the Smith Chart.

Experimentation by variable: series L, shunt C, or shunt C, series L,
could provied a reasonable match. Others probably
have some practical idea.

73,

Frank

Yes Frank I for some reason found myself settlled on 50 0hms impedance
and I can'r remember why and I didn't make a note of it.
In retrospect I should be looking at around 200 plus or minus! This
should not change to repetitiveness of resonances which is of
importance
for all frequency coverage.
So I am going back to the 100 ohm and upwards that I started with and
first check on sw BC and then fine tune on transmit.
I also checked back on the programming and got somewhere near your
figures tho in practicality my measured impedance
were way higher. I suspect the twisting of wires is the culprit for
the differences

"Ch 7 thru 69 DTV"? Only 7-51 is authorized after the transition (in the
U.S.).

<<<<Thanks very much for the info, and that link.

I actually found a simular link, what i can't tell from the above
link, is if it reflects the current state todate or if it is the
planed/proposed listing for after Feb. .

Do you happen to know what that was listed under?? I tried to back
out of the link and just got error msg

thanks again very much

I just use the local 50kw station as a reference. It's hard to see
microvolts from some far away station on a scope, so I just use the
big signals to make comparisons. I can see about 14 stations on a
scope connected directly to the loop, but the amplitudes vary from a
few millivolts to almost a volt.

hook a couple of them up to a rectifier and use them to charge batteries to
power your radio. might as well make some use of that rf that is passing
through you all the time!

I don't know your situation, but many folks can get away with using rabbit ears. It works, or it doesn't. Barring a serious distance problem, a proper antenna may not be needed.

If an antenna made exactly for DTV is cheap, then fine. However, I suspect you may pay extra for an antenna with limited bandwidth over a close out sale on an old fashioned 2 through 82 antenna.

If he hasn't got a variometer he can use his tuner as a substitute.
The SWR meter he is using is referenced to 50 ohms so his readings are
false.
When using twisted wire the impedance will go very much higher than
untwisted wire
at least one hundred times . The impedance of his antenna is probably
around the 300 ohm mark so he should
add a 6 or 9 to one transformer. As a furthur adjustment he can put
the up and down wires in parallell such that the 1100 feet of wire
which is two wavelengths of the top band when wound in series is now 1
wavelength and the impedance will change accoringly. So there are
options available which the ham can chose as well as changing
connections from series to parallel as well as the diferent places he
can add his tuner in the circuit. If he stands the wire tube antenna
upright say as a lamp shade so it appears unobstrusive the radiation
will be omni radial or partialy direcftional if he tilts it and if it
is low power DX that is his hobby then the lower lobe is at least half
of that of a yagi which in his circumstances it should be ideal.Since
the wire is close wound I am not sure of the power limitations but
with it being Hi Temp magnet wire with circuitry of a wavelength I
really don't see a guy in a nursing home having a problem
One thing I am not sure of is the nearnes of the point radiation
antenna with respect to personal health so he may well want to place
it outside say as a frost protector for a rose bush or the like

On the suject of transformers. In the US somebody makes a pre packaged
transformer with five female coax conections depending on the ratio
required,
Since the frequency span is so large as well various locations it may
be that his ratio will land between 6 and 9 to 1
He may want to have ratios that are not as course. What he can do is

to have two rotating contacts ie minuits and hours instead of the single one provided
On the female conectors you place a cent or copper disk in the centre which is your contact The rotary cam that moves the contact around is a 5 pointed star cam with slots from each point towards the center. The outside of the star surface moves a pin around a fifth of the way which is the distance between coax connector. So the switch does not just float across the contact the pin which runs on the cam goes down and up each slot which provides a stop of rotary motionwhile the contact is made. I would not make this until the situation proves that you need it but it does supply matches to with one ohm or so for the intervening distance beteen 6 and 9 to one. One last thing , If power is to be used by others on top band it is adviseable to gang two toroids in parallel
to avoid saturation of the toroidal material. I added the above incase other club members decide to copy with more favourable operating conditions

I disagree on the rabbit ears. If you can do an outdoor antenna it's
preferable for many reasons like less multipath and stronger signal.

> If an antenna made exactly for DTV is cheap, then fine. However, I
suspect
> you may pay extra for an antenna with limited bandwidth over a

> sale on an old fashioned 2 through 82 antenna.

If you don't mind the size of the antenna. The Winegard 7694 is only
35" wide vs 110" for the 7082. There is no such ting as an antenna
"made exactly for DTV". Antennas cover a range of frequencies thet may
include analog or digital TV. Flatness of response and directionality
are the important issues and are equally important for analog or
digital.

Richard Fry wrote:
"The RADIATION performance of a transmit antenna should be considered before anything else."

Yes. John D. Kraus, the inventor of the helical antenna, did just that. In his 1950 edition of "Antennas" on page 176 Kraus wrote:
"The term "transmission mode" is used to describe the manner in which an electromagnetic wave is propagated along an infinite helix as though the helix constituted an infinite transmission line or wave guide. A variety of different transmission modes is possible,

The term "radiation mode" is used to describe the general form of the far-field pattern of a finite helix. Although an infinite variety of patterns is possible, two kinds are of particular interest. One is the axial or beam mode of radiation (R1 mode), and the other is the normal mode of radiation (Ro mode).

Best regards, Richard Harrison, KB5WZI

What a curious indictment of this design. When it "works" (built to
the authur's specification too) it is a false antenna.

Of course, there are any number of oddities struggling for oxygen in
this goldfish bowl.

> he can put the up and down wires in parallell
and it thus fails:
1. to be the loop Guss designed;
2. to be in equilibrium.
>such that the 1100 feet of wire
>which is two wavelengths of the top band when wound in series is now 1
>wavelength and the impedance will change accoringly.
Equilibrium demands 1 wavelength, but the authur allows up to 100%
error. Pretty loose equilibrium there.

So what does equilibrium mean when both a loop of 1100 feet (not a
wavelength at 160M) and half that, 550 feet (not a wavelength at 160M)
are prescribed simultaneously?

When a half-wave, thin-wire dipole is called for, millions of radio
operators for 3 centuries understood that to be 95% of 262 feet
(accounting for end effect). A full wave loop was similarly closer to
525 feet than 1100 feet.

The oddities abound, but those above are enough to ignite a bonfire of
the vanities.

Dear Bob W4NNG: I have been using a Winegard HD-1080. Reflectors behind two, parallel, broadside UHF fan dipoles that each have an extension to help with 7-13. I an using it with 12 and a bunch of UHF channels and it does behave as expected. I would not call it "high-gain," but good enough in this flat area.

Actually, I use a 20 watt solar panel to charge batteries that power a
car radio in my bedroom. At 12 cents a KWH, I figure I save 12 cents

in 50 hours under good conditions, but I don't leave the panel outside all the time, just when the batteries get weak. It's good exercise dragging the solar panel out from under my bed and putting it out in the sunshine, and then putting it away again. It weighs about 17 pounds.

That argument may well be true. Can you name something made in the USA
so I could check it out?

Mostly, I am aware of things with American names, but made in other
countries. Sometimes, you I might be fortunate, enough, to find
something assembled in America--with parts made in other countries.

Like I say, the world looks like walmart, to me--nothing in walmart
(mostly!) has had an American hand in its' manufacture--only its
marketing and retail to Americans ... the actual money is going to
another nation.

No offense intended, but the first really scary thing that I learned as an adult was that there is no "they". It is all random. See, I told you that was scary.

One man's corruption is another man's politics...

Looking back with 20-20 hindsight, it is simple to see how things could have been accomplished in much more efficient manners. Who would have gussed that chemical companies' run-off (ditching) would affect the world so negatively? I lived in a community whose main source of income was the production of various chemicals. Just like the old smoking ads that claimed that smoking was good for you (yes, they did, in fact, exist and were uttered by our government), we blue collar kids were told that chemicals and fumes were good for you. I swear to God. It's true. Seems hard to believe today, but in those days, TV was only on the air for six to seven hours a day and no one, but no one, spread negative news toward industry.

Anyway, we have another chance, in fact, multitude chances, to save our civilization. But it will probably spring from technologies and ways of thinking which we cannot even imagine presently.

Try to enjoy the good things and times while they are here, for they too are transitory. And just in case you forgot, so are we.

Ed Cregger

I got it from www.tvfool.com . Near the top, find "Latest News" and click
"Updated Post-transition Records." On that page, it's the pdf link in the
third paragraph. That paragraph gives you a hint of where it came from:
http://www.fcc.gov/dtv/ but, so sorry, nothing on that page relates.

Furthermore -- and here it gets really depressing -- a search of fcc.gov for
"post transition," shows there's still a steady stream of fresh changes.
Just one, last week, Channel 49 in Bainbridge, Georgia, wants to be channel
50. Not a big Whoop for NYC, but what it really shows is that not

everything is nailed down.

Nothing to do with ground reflection but...

Shunt matching capacitor to raise feed point impedance. But do you need it
in your installation?

I used to use a BC variable cap hooked up to a throttle cable so I could
fine tune my Hamsticks, Yes it made a difference although I never gave it a
Buck Rogers name.

Terman`s 1955 opus on page 929 says:
"In particular, a loop antenna responds much less to the electric induction field than does a simple wire antenna of comparable intercept area. This is of importance because electric induction fields predominate in the man-made noise that causes disturbances in padio receivers, and this explains in part the popularity of loop antennas in broadcast receivers.

Well, I differ, the "they" are those in power with the chance to make
things better, or make a buck--however, we seem to live in a world where
this two things are mutually exclusive! If it were I or you, or we
together, who were the ones in "power", we would face great temptations
to do the same--sell out our fellow citizens to fatten our wallets. The
safeguards, which were once in place, are now gone--money purchasing
your congressmen and senators fixed that ...

We are indeed in a time of GREAT transition. The gold in the gold
fields is gone. The BIG trees in the forests have all been harvested.
In the Sierra Nevada's, "they" have left belts of trees along the
highways for aesthetics, but venture a little ways off these highways
and you find great areas of clear cut land. In the old days, one single
log could fill a logging truck; today, these trucks appear to be
carrying loads of pencils! Every acre of ground is now in the hands of
private citizens, companies/corps or the gov't. All the farm ground is
now in production which is economically feasible to grow crops on; we
tax the reserves of cheaply available fertilizer we have left to raise
these crops. Every gallon of water in the lakes, rivers and streams is
owned by some entity.

Without anymore natural resources to exploit--we now face a much
different world. While capitalism was wonderful when resources were
abundantly plentiful to be raped, it will now be interesting to see how

it functions.

I see a world with vast numbers of impoverished "have-nothings" and a
few members of a ruling class with their knaves and female servents ...
but come hell-or-high-water, we shall see this "new world order." The
gears which bring it turn now; and, I see none powerful enough to halt them.

But then, I digress from antennas ...

I think it's more an issue with being in the "near field" of the interference source, and/or the interference source being in the near field of the antenna. So the relationship between the E and H fields isn't the free space 377 ohms. More of the energy of the interference source might be in the H field than the E field, and the antenna may be more sensitive to the E field than the H field, or vice versa.

Odd, but it was obvious to a lot of people. They were just ignored or
ostracized.

> I lived in a community whose main source of income was the production of
> various chemicals.

In our area, we had a world class trout fishing stream. when I say that, I mean that people from all over the world came here and spent a lot of money to fish, and stay in hotels, eat in restaraunts.

We also had a chemical production company that wanted to do a lot of things that some of the populous didn't want them to do. It got to the point of township meetings. Some folks said that the companies practices were going to destroy the local watershed. The company and a lot of people accused them of being anti-business, anti job, anti growth, and worse.

The chemical company got it's way.

Fast forward to today....

The watershed has been destroyed by two chemicals that leaked from poorly constructed holding areas. The world class trout stream is no more. No more visitors spending all that money - it was millions in the 60's, who knows what it would be now. The chemicals have reached a lake about 30 miles away now, and people aren't supposed to eat fish from either the lake or stream.

And the chemical company? They aren't in business any more. They were bought out by a european company who then closed down the competition, took a write off, and left. That isn't all they left. The bill for the cleanup is with us.

The end result:

Jobs are gone.

World class fishing stream gone.

A nice lake downstream gone as an added benefit.

No one can say they didn't know. They didn't listen.

Just like the old smoking ads that claimed that smoking
> was good for you (yes, they did, in fact, exist and were uttered by our
> government),

And yet, I read a book from the late 1800's that stated that smoking tobacco caused Lung cancer and emphysema, and that chewing it caused oral and stomach cancer.

We knew. We just didn't listen.

> we blue collar kids were told that chemicals and fumes were
> good for you. I swear to God. It's true. Seems hard to believe today, but in

Most look at "the news" on tv/radio, I don't think the answers to their questions are there. I don't think the news is responsible to "Joe-Blow_Citizen"; I think "the news" is responsible to "the men with the money." This is highly dangerous to over 99% of the citizens ... "the truth" can be very difficult to find--when it has the potential to threaten those in power ...

I agree with you here. Even if "the technologies" provide answers (and, that is NOT on the horizon), our "public servants" (the president, senators, congressmen, military, police, etc.) are bought and owned; this is what has really brought on the problems you have named and those which face us now, and in the foreseeable future. Until we have made "them" responsible to us, with great penalties placed on "them" for prostituting themselves for money, we will remain where we are ... the man behind the curtain is pulling the strings and leavers.

What a disaster - and a huge tragedy. Clearly the world would be a
better place....if it was uninhabited.

I guess a better message would have been that holding areas should not be poorly constructed, rather than just shouting the tired old eco-mantra 'corporations are evil' - which nobody listens to. But eco groups aren't exactly the best listeners either.

Channels 2-6 are still allocated to TV, even after 2/09. Only channels
52-69 go away.

Granted, not many major stations are sticking with low-vhf but there
are a few. One of the more notable is WNAZ, the NBC affiliate in
Phoenix which intends to keep using channel 2.

You can check to see what type of antenna you'll need at
www.tvfool.com
You can select either the current stations, or post cutover. For
antenna purposes you want to look at "real channel". Some lucky
markets will be pure UHF after cutover, greatly simplifying their
antenna needs.

Channels 2-51 are all allocated to DTV (except for 37). Channels
2-6 aren't as popular so many people won't need an antenna that can
receive them; some people can even get by with UHF only (14-51). To
be sure about what you will need go to www.tvfool.com and see what
real channels will be used in your area after transition.

Are you certain? I'm in Los Angeles, the #2 market of the U.S., and NONE of our existing stations in Southern California (including the San Diego market too) are keeping their allocations on 2-5 (6 is assigned to Mexico, but even XETV (FOX) is moving to UHF). None of them have even filed construction permits for that range - but have actually filed permits for other allocations (UHF). If there were to be a place where something were to remain in 2-6, I'd think that the top 10 (out of the ~200 TV markets) would have such occur.

"Can`t most of that be accounted for with the loop`s directional properties?"

I don`t have time to verify the answer but will respond from memory. The far fields decline linearly in direct proportion to the distance from the noise source while the near fields decline in proportion to the square of the distance from the source. So an ability to discriminate against local electric near field noise is a destinct advantage separate and apart from any directivity of a loop.

Terman always says what he means and means what he says. He was a sucinct and excellent writer who mastered his topic.

As I understand it-- there will be (more, or less), no TV signals in
the LOW vhf (Channel 2-6), there will be some in the High (Ch 7-13 vhf),
and the bulk of the NEW High Def stations will be in the uhf rangeCh 14,
and up.
BUT to complicate matters, there will be NO MAJOR changes to the
existing NTSC programming , on Cable. Also, IF you are receiveing
your broadcasts from TRANSLATORS, their NTSC, and Freq assignments
WILL NOT CHANGE! Someone into tv broadcasting can give you a better
Defination than I can. As for DTV, to NTSC converters, there is a
$40 Coupon (2 per family) available from

https://www.dtv2009.gov/ApplyCoupon.aspx

Yes, VHF 2 to 6 will be in use after the analog shutdown. There are currently 40 full power stations set to operate on low VHF after 02/17/09. The low VHF channels for digital signals are more sensitive to electrical impulse noise and interference. Few stations in the major urban cities have opted to use low VHF for digital TV because they are most prone to interference there. The largest market station that is currently slated to be on low VHF is WPVI-DT ABC 6 in Philadelphia which will flash cut from UHF 64 to VHF 6 next February.

In a crowded spectrum market such as LA, what may happen is that some low power (LP) stations will eventually be forced to go to low VHF because they can't find any viable upper VHF or UHF channels to be on. But the LPs that do that are going to be stations that really don't care about OTA reception, but want a broadcast station so they can get on the local cable systems - religious stations mostly if I had to guess.

Over 50 stations submitted petitions in June to the FCC asking for a different post-transition channel assignment because their current post-trans channel allotment presents problems for them. A few of these are stations currently alloted to be on low VHF and asked for a upper VHF or UHF channel, so when the dust settles next year (and there will be a LOT of dust), we may have fewer than 40 low VHF full power stations, but they will be there. Many cities will not have any

low VHF digital stations, but will have at least 1 upper VHF station. Hence the need for antenna for upper VHF and UHF.

BTW, low power stations will be allowed to operate on UHF 52 to 59 if they have no alternate good channel assignment, but they also have to have permission from who ever brought the channel frequency to operate there. The last part will likely limit any LP stations in the UHF 52 to 59 range to rural or remote areas, but a LP station in Denver recently filed for a digital UHF 52 channel post-transition.

The more people that want a piece of the pie, the smaller the pieces will be. Our main, number #1 problem is over population for the resources we have remaining and the lifestyle we wish to live. But you know that.

Nature culls its creatures occasionally. Will it be by disease/plague? By wars? By things we cannot even imagine? No one knows. Enjoy the party while it is going on. Analyze later. Worrying hurts no one but you and those around you. I have given up worrying about it all. It is now in God's hands. I surrender.

And that is the answer in a nutshell.

The environmental folks have to make ridiculous statements to the news media to obtain any coverage of their views. The general population sees the wackos on TV and dismisses anything they have to say because, "they aren't like us". But you will never get the general population to think through the unusual clothing, phrasing and behavior of the environmentalists. How can such brilliant folks (the environmentalists on the average) miss such a mundane marketing practice as "do not alienate the customer"? It appears that they could use some help from the very industrial folks they hold in such high disdain.

> groups aren't exactly the best listeners either.

Jim, I'll give you a universal truth. It is all about money. Nothing else. Either through the chemicals or the world class fishing stream.

Take your pick. Have a company that comes in, pays about 20 people a little above minimum wage, and maybe 5 managers a decent wage for a few years. Or a setup that keeps returning money as long as it can be kept up?

Know what the problem with well constructed holding areas is? If you try to insist on them, it will cost the company more money, and in an effort to avoid that, you are painted as an eco-nut or a tree hugger. I was perhaps remiss in that the quality of the holding ponds was part of the controversy. You might be glad to know that the design settled upon saved the company a lot of money. Great, huh? Showed the tree huggers a thing or two. Problem was, it leaked like a seive. Roughty equivalent to just pouring th echemicals on the ground, which would have saved the company even more money.

Contrast that to millions that would have come in if the fishing stream was protected and maintained.

As a person who stood to make money on one of the two endeavors, which would you prefer? One that could make you a whole lot of money over a long long period of time, or the ten year model that puts a lot less money into the community, eventually leaves you footing a very large bill. What we did, we lost money on, not made money.

No tree hugging, no Sierra club, no leeeburuls, no "Corporations are evil", nothing but pure bottom line. Money. Why would you be against making as mouch money as possible? I like capitalism myself, how about you?

Yes, a disease which favored the control freaks, corrupt public servants
and the power-hungry would be useful right about now ...

And yes, something new, unique or at least interesting and not seen
before would be nice--even with antennas! I am all ears! :-)

Warm regards,
JS

Then I suggest you listen to rush linbaugh (sp?) He clearly explains that there is nothing wrong; things are good and only getting better!

However, I think he is mainly speaking to those which enjoy the smog polluted airs of Los Angeles and drinking water containing chemicals I have great difficulty pronouncing. Those who think the climbing numbers of sterile males is "natural." Those who like the charts showing climbing numbers of cancer, birth defects, etc. Those who never did like the taste of salmon and can certainly rejoice in its' extinction, etc., etc.

You know who I speak of, those who will only empty the trash can when garbage starts hitting the floor and stinking so bad it takes their breath away, and they ponder why the rats have taken on such a sickly look ...

Regards,
JS

After February 2009, some DTV stations still will be on lower VHF (Channels 2 through 6. See
http://fjallfoss.fcc.gov/edocs_public/attachmatch/FCC-07-138A2.pdf
Look up your city in this URL; you may find that you need a Low VHF antenna also. For example, in Las Vegas (near where I live) NTSC Channel 3 will be on Channel 2 broadcasting DTV.

All active analog stations with a digital signal are broadcasting
that digital signal on a different channel. The ATSC tuners maps them
to the displayed channel number. Some 500 stations will flash cut
their digital signal back to their analog channel next February after
the analog shutdown, but the vast majority of the low VHF analog
stations will have their physical be on UHF or upper VHF.

In the San Francisco market,
KTVU-DT Fox 2 is currently on UHF 56, will move to UHF 44 next year.
KRON-DT MyN 4 is currently on UHF 57, will move to UHF 38 next year.
KPIX-DT CBS 5 is currently on UHF 29 and will stay there next year.
KGO-DT ABC 7 is currently on UHF 24, will flash cut to VHF 7 next
year.
KNTV-DT NBC 11 is on UHF 12 and will stay there next year.

The San Francisco market has perhaps the most complicated transition
of any city in the US next February and in the months afterwords,
Stations will be putting up new antennas on the Sutro Tower, taking
old ones off, moving to channels currently occupied by other analog
stations. Many stations will be using their backup reduced coverage
antennas in the daytime when the tower is being worked on.

The primary redeeming quality and prerequisite of any good mantra is
that it must fit nicely on a bumper sticker - inescapable logic in
four words or less. Print enough of them and it becomes a truism.

Never trust anyone over 30, man.

John Smith wrote:
"It sounds logical anyway."

B. Whitfield Griffith, Jr. confirms rates of near field and far field decline in "Radio-Electronic Transnission Fundamentals" on page 323:

"As the distance from the antenna is increased, the induction field is found to diminish quite rapidly; in fact, its intensity is approximately proportional to the inverse square of the distance. In the region very close to the antenna (at distances of 1/8 wavelength or less), the induction field is very strong and may cause induction of large voltages or currents in nearby conductors."

Best regards, Richard Harrison, KB5WZI

| Channels 2-6 are still allocated to TV, even after 2/09. Only channels
| 52-69 go away.
|
| Granted, not many major stations are sticking with low-vhf but there
| are a few. One of the more notable is WNAZ, the NBC affiliate in
| Phoenix which intends to keep using channel 2.

Usuaully its the stations the FCC did a screw-job on. They already had
low-band analog and were given either a low-band transition or a depricated
UHF transition in 52-69.

Congress should have mandated that the FCC find space on high VHF or UHF for
all stations that wanted it, with an emphasis on making a market have all on
UHF where possible, and where not possible, put many on high VHF so that not
a single station is alone there.

Most markets in the USA have to deal with issues from stations in all directions
around those cities. Los Angeles doesn't have to deal with stations to the west.

Yes, but one could take consolation in the fact that with enough self-
righteous indignation and proselytizing, there would eventually be a
law against it.

That is NOT a safe bet, depending on your local stations. Two of our
local stations will be reverting BACK to VHF at that time. They are on
UHF now. So before telling someone that they will not need the "longer
elements" (VHF), it would behoove them to check and see just what their
local conditions will dictate.

Our local ABC affiliate WOI is reverting from UHF to VHF channel 5 in
Feb 2009. It's nuts, but that's what they are doing. Nother station is
going from UHF channel 31 to VHF channel 8...so it is NOT unheard of and
those who blindly go UHF only in an antenna without knowing what EXACTLY
their locals are going to do may find another antenna purchase in their
future.

Which will do no good here at all. Post transition our local ABC
affiliate is going to VHF channel 5.

There is no substitute for the long tried and tested combo vhf/uhf
antenna in our area.

Phil,

Some stations wanted to remain on the low VHF channels for power and propagation reasons. Some broadcasters in the Midwest with large coverage areas get a lower electric bill on those channels even though the threat of interference is higher. Interference is a bigger problem in metropolitan areas than it is in the flat rural corn fields of the U.S. bread basket.

David

That is NOT correct. our local ABC affiliate is currently on channel 56
UHF and will be reverting to channel 5 VHF in Feb 2009. (at least that's
what they are telling us)

534. 11 meter beam

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-17 22:37:40 UTC
From: Stan Cooper <Stan@nospam.com>
Message-ID: <g5ohjn$ru7$1@news.albasani.net>
Source record: 23908

Hello I hope I'm not intruding by asking for advice on a CB antenna but I figured this would be the group to ask about such things for the straight scoop. At any rate I'm considering a store bought beam with both vertical and horizontal polarization and my choices are limited to these two below. (not many being manufactured anymore)

The Maco has a 16 foot boom and an advertised gain of 12.5 db, while the JO GUNN has an 8 foot boom and an advertised gain of 14.5 db. I know there is a lot of smoke and mirrors involved with advertised gains and so my question is...is it possible for the JO GUNN to perform as well as the Maco antenna?

The GUNN is of much stronger construction and a smaller windload so I'd rather put it up, but the short boom makes me wonder if the gain and rejection numbers are suspect.

Any help would be greatly appreciated, antenna choices, price tags and urls below.

73
Stan

MACO-Shooting Star $279.95
http://www.mpaudio1.com/Macobeamantennas2.html

JO GUNN 3 + 3 STAR $382.00
http://tinyurl.com/6hzteu

Oh btw, I'll be tower mounting it about 40' from the ground and turning it with a hamIV rotator.

Thanks again.

Choose MACO for three reasons:
1. They understand the dB relationship to power gain;
b. their dB isn't relative to TRUE (whatever that means);
iii. it's cheaper.

On the negative side, neither seem to be acquainted with the dBi or
dBd basis of comparison (giving them the appearance of being yokels
selling out the trunk of their car). Imagine, having more "audio
gain" than rf gain from an antenna (do they inluded phased speakers?).

A claim of "2kw power handling capability!" is to suggest this is
part of the gain package? Don't exceed 2kw/28 input power?

Howabout "quad reflector to obtain the best combination of gain and
front-to-back ratio." Why not fully quad design to obtain the best
combination of ALL gains?

What's the difference between FRONT TO BACK RATIO and BACK REJECTION?

> Maco antenna?
>

well, there are a couple possibilities... first the Maco could be poorly designed so it doesn't perform as well as the JO GUNN, or the Maco advertisers could be more honest than the JO GUNN ones are... or the JO GUNN is extremely well designed, or their advertisers aren't as honest as the Maco ones are.

OR, they could just be comparing to completely different references, thats the basic problem with antenna gains, they usually don't tell you what they are compared to if the JO GUNN was compared to an isotropic radiator where the Maco was compared to a dipole that buys them a couple db right there.

confused yet? there's even more...

Maybe the JO GUNN is measured over real ground at the best height and elevation angle they could find... and the Maco was measured in free space. Measuring an antenna over real ground and finding the max gain lobe could give the JO GUNN a whole bunch more gain than the free space Maco... enough to make up for half the boom length and a worse design put together.

So there you have it... my suggestion, put up a ground plane to talk to your local buddies and get a ham license so you can legally and openly talk around the world.

Stan;

I don't know if you have considered it but I would like to suggest that
you look into ham radio. It is a more adventurous hobby,one that offers
greater opportunity to exercise your operating skills. By and large the
licensed ham radio operators offer a courteous, friendly and extremely
helpful environment. I have to assume that since you are here looking
for assistance you already have a feeling for all this.
Getting a ham license has never been easier. There are only three
classes of license now, Technician, General and Extra. The code test has

been eliminated so that shouldn't be a problem. The tests are multiple choice and have a minimum passing level of 80%. That works out to be 28 correct answers for tech and general out of 35, the extra test has 15 more questions and so requires 40 correct answers. All questions are published and if you go to http://www.qrz.com you can take sample tests. Take enough samples and you should be able to pass the exam. Go to http://www.arrl.org for locations and times for exams. There is a cost for the exam but it isn't much.

Now as to your question. There isn't much to recommend either antenna. They are based on designs used in the ham radio field. You might look for these antennas and compare the numbers there. A source of ham radio equipment is www.aesham.com. This is one of the premier ham radio houses.

Good luck
Dave WD9BDZ

I would be sceptical. The fact that both manufacturers are quoting gain in dB, without saying what it's in reference to (dBi for isotropic, dBd for dipole) is a bit of a warning sign. Assume it's dBi - the numbers come out bigger, and that's attractive in ads.

I'd be sceptical of the numbers offered for both of these antennas, but I'd be quite a bit more sceptical concerning the JO GUNN.

It's probably useful to compare the design, and the numbers, with what's known and published about various reference Yagi designs and the results that can be achieved. I looked at some of the documentation that Cebik (SK) published on his excellent web site.

The Maco is advertised as a "6-element" antenna, but the drawing doesn't show a full set of six elements on either vertical or horizontal polarization. I can't tell whether they omitted showing some elements to leave the drawing less cluttered, or whether it's supposed to be a "three elements vertical plus three elements horizontal, equals six elements" design. It looks to me as if it's essentially a Quagi antenna - a quad element in back (reflector?) plus one or more set of linear elements in a Yagi-style arrangement.

At 11.5 feet, it's about a third of a wavelength long... and for any antenna of this general type, the boom length is likely to be the parameter which dominates the maximum gain figure you can achieve.

Cebik's figures indicate that well-designed quarter-wavelength-boom Yagis typically deliver somewher around 8 dBi of gain, and one-half-wavelength-boom Yagis are up somewhere around 10 dBi. Front-to-back figures in the 25 - 35 dB range seem to be achievable. There's usually a tradeoff in the optimization process... for any given boom length, optimizing for maximum gain will usually cost you F/B ratio, and vice versa.

I'd guess that it's *possible* that the Maco actually achieves 12.5 dBi of gain (at least on paper) at some frequency with its one-third-lambda boom length, but that's more than I'd expect.

This assumes that the Maco has separate feeds for horizontal and vertical polarization, and that it feeds only one at a time (e.g. via a switch) and that there are no losses involved. If it's actually feeding power to both polarizations at once (either linear or

circular), subtract 3 dB from the effective gain to a
linearly-polarized vertical or horizontal antenna at the other end.

The JO GUNN... well, I'm not sure just what sort of antenna it thinks
it is, other than "tries to be snazzy looking". It seems to be a
three-element short-beam antenna (at 8 feet it's less than 1/4
wavelength long), and yet it's claiming a 14.5 dB gain. This is
around 6 dB more gain than Cebik indicates is delivered by Yagis in
this boom-length class. The F/B ratio, "side rejection" and "back
rejection" are all extremely high (40 dB)... such high numbers suggest
that these are the best-looking numbers, taken from the deepest
rejection lobes of a mathematical model of the antenna in free space.

>The GUNN is of much stronger construction and a smaller windload so I'd
>rather put it up, but the short boom makes me wonder if the gain and
>rejection numbers are suspect.

Well, before I trusted these numbers at all, I'd want to get a NEC2 or
similar model of the antenna from the manufacturer, and run the model
myself.

My guess is that the Maco folks *might* give you a model deck if you
ask nicely, and that the JO GUNN folks with either refuse or say "What
are you talking about?" or claim that their antenna incorporates
principles that cannot be accurately modeled.

Stan, just go with what you like. I too am suspicious of claimed gain by manufacturers.

I will also throw in a plug for getting your ham license. It costs very little to get your license, and it opens many new adventures far and above 11 meters. You can work the world on 100 watts and a wire strung between a couple of trees.

Try the practice tests on QRZ.com.

Hi Richard

Isnt there a difference there? (I'll admit I dont think in these terms. I use the actual pattern instead)

Isn't F/B a comparison of "forward" vs "backward" at the optimum/best case "single angle" and Back Rejection (or some other name) the comparison of all radiated power forward vs backwards?

Many parasitic designs end up with very good F/B but as soon as you go off a few degrees a rearward lobe comes into play.

Hi Stan,

The Maco Shooting star "data" says it has a gain of 14dB (the Comet is the
one rated at 12.5dB). Both manufacturers claim decibels of gain as well as
power gain. The relationship is logarithmic, where dB = 10 log(base10)
P1/P2. The Maco Shooting star claims 28X power gain. This would be
14.47dB... close to what they claim. The JO GUNN 3+3 Star claims 40X power

gain. This would be 16.02dB... 2dB more than what they claim. The Maco item doesn't make any claim about Front/Back or Front/Side rejection, while the JO GUNN item makes some very wild claims of over 40dB. Based on this information, I'd probably go with the Maco.

The late William I. Orr said it best in the preface to his book, 'The Truth About CB Antennas', "PT Barnum is alive and well, and writing CB antenna ads."

I have never ran either one. However, I would go with the MACO also--if forced to choose on the data which has been presented, alone ... It is a four element antenna, the JO GUNN is three and in an unconventional configuration.

The MACO, on the other hand, appears to be completely switchable from vertical mode to horizontal mode.

Hi Bobï¿½,

If you examine the specifications for both, they reveal exactly the
same value. It follows they measure the same thing but use different
terms (one can only imagine they have ad writers who find their
inspiration for straining terms in claims for Gussian antennas).

There are very few antennas with a null located at 180ï¿½ (Cardioid
comes to mind); and, as you infer, it quickly disappears off
boresight. Further, your suggestion of average forward compared to
average backward is, perhaps, a useful indicator. However, neither
supplier appears to interested in averages.

I used to work at a low band VHF station that was running 56 kW ERP.
The actual transmitter output was 8kW visual and 2.3 kW aural. When I
bellyached that KABC 7 in LA would be running only 13kW DT, Alan
Figgatt pointed out that DTV doesn't require as much power as analog
and 13 kW should be good here. The point is that from a power
standpoint, VHF-lo vs VHF-hi wouldn't be all that big a deal. The
station gear and A/C would be a much bigger load than the actual
transmitter. Compare that to analog UHF where 55 kW visual and 10kW
aural is common. THOSE folks will see a big savings but compared to
the power load when all the studio lights are on for a production or
newcast, even 65 kW is a big part but not the biggest. HVAC can be a

bigger load issue - particularly with VHF-hi where 13kW ERP may only need a few kW of acutal transmitter output.

I hope I don't hear how the DTV breaks up a lot during lightning strikes. I know that on VHF-lo analog you get LOTS of 'sparklies' during lightning storms.

Dear "me" Not big at all. It is intended for high VHF and UHF. I have it mounted on a tube that is supported in turn by the top section of a tower, which became surplus after a rotator change. The whole assembly is in a second story room with the main computer and can be rotated by hand.

It is deceptive to put numbers on the size. The reflector consists of five doublets each with a tip-to-top length of 26.5 inches and a total height of a little over 16 inches. The twin "driven" elements are spaced about 6.6 inches in front of the reflectors (obviously the reflectors are only effective for UHF). The tip-to-tip length of the driven elements is about 34.5 inches (giving a predicted 0.5 WL resonance towards the bottom of the higher VHF TV band). Each driven element is coaxial with a fan dipole that should have a resonance somewhere in the UHF band. Thus one expects a small gain with a small F/B in the higher VHF band and fair gain with good F/B in the UHF band.

I hope that this is of some assistance. I regret that you believe you must be anonymous.

Regards, Mac N8TT

When you are measuring gain, if dBi isn't specified it is normal to assume dBd. I cannot get that JoGunn page to load and display, but based on what you have said, the better, or should I say, more believable one is the Maco. Those gain numbers seem high by a bit for a four element antenna, but there may be some advantage from the dual polarity, but I doubt it, as the power is split between Hand V as well going in. And 4 elements/16 foot boom, 27 MHz sounds much closer to right than 8' boom 3 elements and 14 db. Those are just plain wrong, or at least lack reference.

The ARRL handbook years ago had a construction article on a ten meter beam, that I scaled very successfully to 15 meters. 12 foot boom three eleemnts, made from basic aluminum tubing, probably cost well under $100 to build today. But you'd need to be handy with a 'grid dip meter" to get it right. Just another thought.

My $0.02

RE: getting ham license and operating ten meters, I'd guess you're actually interested in talking to someone, so 11 meters is probably better for that. I frequently listen on 27.185 as an indicator of weather or not ten meters is open. Lots of activity from about 26.8 thru 27.6 or higher, nothing above 28 except some lonely beacons...true shame. But if you go beyond the ten meter deal, and get with the other HF bands or 2 meters, 440, etc, you'll have a blast, and the code no longer stands in the way...

Good luck with the Maco.

George,

Fundamental relationships depend on dBi, it is dBd that is the fudge.

dBd seems to have its popularity from the mistaken view by some that
because it is not possible to construct a real isotropic radiator, that dBi
doesn't have a real meaning.

Stan
The Maco antennas are built here in Memphis, and are not of a high
quality. If
I had to use one of their products, it would be a pair of
horizontal-stacked V-quads.
Small, light, works well and can be easily re-tuned to 10 meters later on.
The Jo Gunn model is a copy of the Charles "Gizmotchi" antenna (still
being made,
by the way). Construction is better, tubing fit and finish are quite good,
but the gain
figures are really about 7 dbi for both of the antennas.
Gain figures are inflated to catch a sale, so I'd consider quality,
price, and strength
of materials/design as more important factors.
I've got enough tubing in my antenna junk to build a 3 element Gizmotchi
for 10
meters, and I might just do that, for the sake of having something different
in the
neighborhood.

You are aware that channel 8 is NOT in the 2-6 segment (VHF-low), so that is
irrevelant.

Channels 2-4 = 54-72Mhz.
5-6 = 76-88MHz.
7-13 = 174-216Mhz.

All active analog stations with a digital signal are broadcasting
that digital signal on a different channel. The ATSC tuners maps them
to the displayed channel number. Some 500 stations will flash cut
their digital signal back to their analog channel next February after
the analog shutdown, but the vast majority of the low VHF analog
stations will have their physical be on UHF or upper VHF.

In the San Francisco market,
KTVU-DT Fox 2 is currently on UHF 56, will move to UHF 44 next year.
KRON-DT MyN 4 is currently on UHF 57, will move to UHF 38 next year.
KPIX-DT CBS 5 is currently on UHF 29 and will stay there next year.
KGO-DT ABC 7 is currently on UHF 24, will flash cut to VHF 7 next
year.
KNTV-DT NBC 11 is on UHF 12 and will stay there next year.
...

Which, for the clueless, means NO DTV on 2-6, which is exactly what I said.

Since he did not say where he is, your answer may be wrong. While I agree with it in principal, not everyone has it so easy. Here in Israel there still is a code requirement, testing is twice a year, and ANY permanent antenna requires a permit which no one seems to know how to get. Technicaly any operation over 20 watts EIRP requires radiation level certification.

But then CB is just as bad. Except for a few off-roaders who have not gone to 446 mHz it's even deader than ham radio.

At least one manufacturer has taken advantage of the fact that, unlike dBi, dBd has no universal definition. Some think it's dB relative to a dipole in free space; others think it's relative to a dipole mounted over ground. And few seem to realize that the difference between the two is typically 4 - 6 dB. Creative marketeers are able to capitalize on this confusion, and have.

Hi Stussy. Well I see that HDTV arrangements are just as chaotic in the
us as they are in NZ. Even now many in the trade are still "guessing".
We have allocated 6 UHF channels for HDTV but since NZ is a very hilly
country this gives only patchy coverage out to about 50Km with a lot of
dead spots. At least we are keeping SDTV running for a few years yet on
VHF and UHF.
Where I live about 55Km from Auckland we can't get solid HDTV reception
and they aren't using satellite HDTV for free to air Tv for a while, so
we will have to wait despite having a suitable RX.
Let's hope they sort themselves out soon everywhere, though I fear that
things have been allowed to become too disorganised.

Since late last year, rumors have been circulating that a major network or cable station was going to do a special on tower erectors.

NBC confirmed it today, and their "Tower Dogs" special will air on July 21 at 10 P.M/ET.

For an overview of the one hour special, the background on the producers and some production shots and notes, see:

If it is going to be a either temporary or permanent you might want to use the first line up to hold a pulley, then run the antenna line thru the pulley. Another way is to run your line thru a couple thickness of plastic tubing positioning the tubing over the branch to keep the line from digging into the bark.

Also, if you have a old spare bowling ball (don't laugh), either the 4lb (duckpin) or the 16lb (tenpin) they make great weights for the end of the lines instead of having to use a pail with cement for the weight with eyebolt. Most of the bowling balls are made from hard rubber - all you do is drill a hole and insert some epoxy glue or super glue in it and then screw-in an eyebolt type of screw! When the wind blows and the tree sways the antenna line should remain constant. Make sure that the line is about 3 - 5 ft above the ground when using a weighted system.

Geoff;

Your are right in one sense, however the antenna's in question are, I
believe, USA products so it is fairly save to assume that the writer is
a USA resident.

From your comments I assume (that word again) that you are a resident
of Israel. Given the situation there I can see why the government would
try to make it hard for someone to install and operate a radio station.
I look forward to the day when everyone in the Mideast can live together
in peace and harmony.

Until that time thank you for your comments.

We’re a video game specialist and wholesaler for modded consoles, retro consoles and game backups, we ship worldwide. Below are some of our offerings at wholesale prices. For any enquiries, please feel free to contact us at gamersparadisemy@gmail.com

Sony Playstation 3 - 40GB Pack (NTSC/U & NTSC/J versions available) comes with two dual shock 3 controllers and Hori cooling fan.
USD 350 (with worldwide shipping)

XBOX 360 Elite (with HDMI)
– 120GB Pack (NTSC/U & NTSC/J) comes with two controllers and Nyko cooling fan.
Modded and able to run XBOX 360 backups, homebrew softwares and able to go online via XBOX Live.
USD 400 (with worldwide shipping)

XBOX 360 Premium (with HDMI, free 2 ori games, Forza 2 and Viva Pinata)
– 20GB Pack (NTSC/U & NTSC/J) comes with two controllers and Nyko cooling fan.
Modded and able to run XBOX 360 backups, homebrew softwares and able to go online via XBOX Live.
USD 330 (with worldwide shipping)

XBOX 360 Core (without HDD and HD cable, only composite video)
– (NTSC/U & NTSC/J) comes with 1 controller.
Modded and able to run XBOX 360 backups, homebrew softwares and able to go online via XBOX Live.
USD 260 (with worldwide shipping)

Nintendo Wii - (NTSC/U & NTSC/J) comes with two controllers and Nyko cooling fan.
Modded and able to run Nintendo Wii backups and homebrew softwares.
USD290 (with worldwide shipping)

Sony PS2 - (NTSC/U & NTSC/J) comes with two controllers and Nyko cooling fan.
Modded and able to run PS2 backups and homebrew softwares.
USD140 (with worldwide shipping)

Sony PSP with 4GB MSPD
Able to run PSP backups and homebrew softwares.
USD180 (with worldwide shipping)

Nintendo NDS Lite with R4 (2GB MiniSD card included)
Able to run NDS backups and homebrew softwares

USD180 (with worldwide shipping)

*** Remarks: All modded consoles come with 5 backups of your choice
whereas for portables, they will come with 5-10 preloaded games of
your choice on the memory card.

XBOX 360 / Wii / PS2 Backups,
USD2 each (dvd-r), USD3 each (factory pressed gold disc) – minimum
order of 10 games needed.

NDS / PSP Roms
USD2 per game, burnt on dvd-r, USD5 for any 3 games burnt on dvd-r

---

Used Retro Consoles, Original Games & Backups
(Please email us for the best price, we have many used retro consoles
and games in stock, all in perfect condition, sourced from Shibuya,

I see only 1 ABC affiliate going to VHF 5 post-transition and that is WOI-DT ABC 5 in Des Moines moving from UHF 59 to VHF 5. Is that your local ABC affiliate? The FCC database shows WOI-DT with a low STA (Special Temporary Authority) power of 500 Watts on UHF 59 which is a very weak power if correct.

The good news to some extent is that WOI-DT was granted their request to run at an increased power of 8.2 kW (up from 3.91 kW) for the post-transition VHF 5 allotment which is a good power level for digital low VHF. In Des Moines, IA, there should be a number of open channels to broadcast on UHF if WIO wanted to.

This portable antenna can be used for the top section of a Vertical Antenna
OR Horizontal elements for an Antenna System such as the Buddipole tm
..... A Great QRP / Portable Antenna weighs only 400 Grams [14 Oz]
and measures 104" extended yet only 14" long when folded. Picture
The construction is the same as is used for sectional fishing poles. Each
of the 8 hollow tubular metal sections has a plug one one end and a socket
on the other end. All the sections are connected by a string made of either
a cloth or metal cord. At the bottom of the base element there's a spring
inside the tube to tension the cord. Some units may use an elastic
shock-cord material. This way all the elements are kept in order when
they are disconnected from each other and are held together when assembled
into a 104" [8.6 Ft] long antenna. When the elements are folded or
disassembled the package is only 14 inches long.
The base has a male 3/8-24 thread which is the same as is used on most Ham
Radio and CB antennas. Some sort of spring base could be used when this
antenna is used because the hollow antenna elements will "fold" if too much
force is applied to them.
These units are in Like New Condition.. Sold AS-IS but will not be DOA.
ONLY $30 Plus Shipping

> what they are telling us)

Document http://fjallfoss.fcc.gov/edocs_public/attachmatch/FCC-07-138A2.xls
is an 1800-record spreadsheet listing the current and proposed channels. Do
what I did and sort it on the NEW DTV channel numbers. You will discover,
as I did, that only a few dozen stations were headed for low-VHF after
transition.

Here are the actual numbers (after the sort):

Records 1 to 37 are on TV Channels 2 - 6
Records 38 to 487 are on TV channels 7 - 13
Records 488 to 1811 are on TV channels 14 - 51

http://fjallfoss.fcc.gov/edocs_public/attachmatch/FCC-07-138A3.xls appears
to be a minor supplement to the big guy, having only 16 records:

Records 1 is on TV Channels 2 - 6
Records 2 to 5 are on TV channels 7 - 13
Records 6 to 13 are on TV channels 14 - 51

Trying to nail this down any better is like trying to nail Jello to the
wall.

According to the info I have, NYC stations will be on UHF, except for CH7, 11, and 13, which will revert back to the present analog channels. All NYC channels are on UHF right now.

I thought so, but sometimes the people asking are not. They only have
access to U.S. manufacturer's products and catalogs via web sites,
with no local dealers.

> From your comments I assume (that word again) that you are a resident
> of Israel. Given the situation there I can see why the government would
> try to make it hard for someone to install and operate a radio station.

Well, actually it's not. The antenna restriction is because the
"cellphone towers will kill you" people have forced laws through to prevent
anyone setting up a radio transmitter in their neighborhood.

The morse code requirment is because the people who run the Israel equivalent
of the ARRL pushed the Minstry of Communications to keep it. It keeps out
new hams from foreign countries. I have no idea how they handle visiting
operators now.

> I look forward to the day when everyone in the Mideast can live together

I have finally got my Cushcraft MA5B up in the air. But I am very disappointed with it.

Is it normal for this antenna to have a lot of background noise behind strong signals 9+?

The reason I ask is that I also own a cobwebb antenna and the side by side comparison between them, there is no background hiss on the same strong signals on the cobwebb S4 - 9+ but there is on the same signal on the MA5B and it is enough to make listening on the MA5B very unpleasant even at S9+.

Is this normal?

Hi to all

When running a length of TX line through an environment where it is susceptible to contact leaves or maybe branches, what is the best choice.. window ladder line or coaxial wire?

In other words, will both of these type of lines have about the same loss to natural environment objects or is one more sensible than the other?

I am not talking about SWR losses or matched line losses.

Thanks de VE2PID

If no common-mode currents exist on the coax, it will
be impervious to environmental losses. Under ideal
conditions, 100% of the energy fields are confined
inside the coax. That is not true for ladder-line whose
fields around the wires should be kept some distance
from environmental objects.

A very 'general' answer is that coax will have less 'variable' loss
from being near stuff than 'ladder-line' because of the way it's
constructed (and why it was originally made anyway). If that's the
only consideration you have to think about, then it's a fairly simple
question to answer. When you start thinking about the other
properties/characteristics of coax/ladder line, the answer isn't quite
so simple any more. (I like using ladder line, but I seriously doubt
if I try running it in a vehicle, see what I mean?)
- 'Doc

I've found that a 10ga loaded with small shot will clear out most
leaves that might interfere with ladder line. Large twigs, limbs,
etc, require larger shot. Gotta get that angle right though, that's
the hard part. Not to mention the neighbors...
(No, I'm really not that dumb. Just depends on how frustrated I am.)

Andy,
This is pure speculation so take it that way. I've noticed that any antenna with 'sharp points' associated with it has typically been noisier than antennas without those sharp points (capacity hats in this case). That's certainly not 'definitive' in any way, so... speculation. Also, considering where those cap-hats are mounted, using a very smooth huge ball instead of those 'sharp-points' is sort of dumb. So they did the best they could, right?
- 'Doc

(Completely beside the point. Once used a very large metal ball as a capacitive hat on a mobile antenna. Worked fine sitting still. Not very broad banded, but certainly shorter than the usual whip. Absolute catastrophe when trying to drive! Didn't last long at all.)

Hello Stan:

Try to find a Hy-Gain 3 element yagi beam that uses the Hairpin Matching system. And use the Hy-Gain Balun. That way you won't have the significant loss of the Gamma Match.

Twinlead/ladder line comes in handy for situations such as mine.

I'm running a Van Gordon All Bander dipole. Fed with 450 ohm twinlead, which it is, I can tune virtually anywhere from 160 meters to 6 meters as long as I'm tolerant of a bit of RF in the shack. To me, the versatility of being able to transmit anywhere I'm legal from six meters down to 160 meters is well worth the pattern changes and other characteristics of the dipole/twinlead combination.

Just be aware that you can enter into situations with this setup that can start a fire by arcing to an interior/exterior object if a kilowatt or more is used. Maybe even less power, come to think of it. I set a curtain on fire once this way. That was an interesting sounding transmission after I saw the curtain ablaze.

For me, this setup works the best for my circumstances.

Feed this same antenna with coax and you'll run out of tuner swing long before you'll match the same antenna to the same bands as matched with twinlead. Chances are you'll also punch a hole through the coax' dielectric insulator, which leads to breakdown (internal arcing) at even lower voltages later on. Coax has its uses and I use plenty of it for the higher bands. Just not on the low bands since I must make do with my single Van Gordon All Bander antenna.

I apologize for not sounding as scholarly as many of you, but I'm getting old and don't have time for that nonsense. 8>)

Yes, that is the station and they have applied for a further increase in power to around 13 kW, but I don't know if it has been granted. So, we do have a low band vhf station that will "appear" in Feb 2009. I am at a total loss to explain why they made this decision...it is likely to reduce their footprint significantly. Channel 8-1 is doing the same thing, moving from RF Ch 31 to RF Ch 8, at the same time.

Ch 5 analog has been famous for years here for having a rotten signal. When they went digital to 5-1 on UHF, they skyrocketed and have been solid....now they are going back and probably in the toilet again. Thank God ABC lost Monday Night Football.

Unfortunately the one station on two through six, is our local ABC affiliate Ch 5, WOI-DT....their signal is going to go into the toilet, running low power on the vhf low band. (also, most modest to largish TV antennas have very low gain and a lousy pattern (horrible for multi-path)on Ch 5 and below. Go figure!

Dunno. Doesn't really make sense.. As far as receive, there should be
little difference between the two as far as s/n ratio.
I'm not sure if I'm buying that it's corona buildup. That would
depend on your climate, wx, etc..
Being as you seem to notice it most on the strongest signals,
I'd have to ask one thing first.
Is your noise blanker on?

The short answer is coax.

When properly balanced (that is, common mode current suppressed), coaxial cable is totally insensitive to its electrical environment. Ladder, window, and other types of twinlead line, however, are not. They're most susceptible if the line has a high SWR and the contact with water, other lossy material, or conductors occurs near a voltage peak, but even when matched, considerable loss and/or impedance disturbances can occur. There's very little good data on the effect of water, but I made measurements of TV twinlead many years ago and found that it could be lossier than even small coax when wet. Wes Stewart measured some ladder line and found that it also could be quite lossy when wet. He posted the results on this forum some years ago. While the loss specifications of dry ladder line in an ideal environment are attractive, it can easily become much lossier than coax when wet and in close proximity to lossy materials such as leaves or damp wood.

I've got a UHF TV antenna that I use for 420 mhz ATV
reception. It's one of those corner reflector type deals
with a lot of elements.
In comparing 300 ohm twin lead vs 75 ohm coax, the
twin lead had the lowest loss when dry.
Or at least with the Belden "duo-shield" cable I was using.
But if it got wet, the twin lead loss was quite major.
I'd go from a clear picture to half snow..
I'd have to wait for it to slowly dry off to get my picture back.
I don't really use much ladder line as I prefer coax
for my everyday antennas.
But if I did, I would use a line with mostly air between
the conductors. Which means I'd probably make my own.
But the ladder line with the gaps in the plastic would
be better than twin lead.

WOI-DT applied for a 11.5 kW ERP on VHF 5 in June, but the FCC has not
granted or rejected the application yet. The only real reason I can see
for going to low-VHF for where they are is to save money by re-using the
VHF 5 antenna & transmitter and for the lower operating costs of low
VHF. Their UHF 59 digital signal is out of core, so they have to give
that up. If they have interference problems for analog on VHF 5, that
won't go away for digital VHF 5.

You have 3 stations in Des Moines do a digital flash cut to their upper VHF analog channel. Upper VHF at 174 to 216 MHz (compared to low VHF at 54 to 88 MHz) is considered a good band for digital broadcasting.

KCCI-DT CBS 8 will move from 31 to VHF 8 at 23 kW ERP.
KDIN-DT PBS 11 will move from UHF 50 to 11 at 19.8 kW, but plans to operate on UHF 50 for a while after the analog shutdown for VHF 11 antenna work (http://fjallfoss.fcc.gov/prod/cdbs/forms/prod/getattachment_exh.cgi?exhibit_id=618292).
WHO-DT NBC 13 will move from UHF 19 to VHF 13 at 29 kW ERP.

All 3 of them will have respectable power levels for digital upper VHF. I also see that KDMI-DT My Network 56(?) will take over KCCI's RF 31 antenna and transmitter. Good luck with WOI-DT reception after they switch.

Hi all,

I post this here since probably here lurks a good amount of smith chart and transmission lines wizards.

I was trying to make a simple two stub filter with coaxial lines, basicly it would serve as 88-108 MHz notch with a working frequency of 70 MHz.
The filter is like this:

```
< length A>
rig--|---------------|--ant
| |
b | | b
| |
```

The two "b" stubs are 64 cm cellflex 1/2 inch, with the antenna analyzer they measure R=0 X=21 at 70 MHz, almost as they should per a quick smith chart check, they should be 1/4 lambda at 98 MHz, open at the end.
Now with two of these stubs the lenght A that gives a 50 ohm match should be 0.378 lambda as per the smith chart calculation.

In real life with that value for A the only 50 ohm match (substituting a dummy load for ant and the analyzer on the "rig" port) is around 36 MHz.

What doesn't seem to agree between theory and practice is that measuring any "b" stub in parallel with the dummy load shows an impedance of about R=11 and X=11, while on the smith chart this should be R=11 and X=21 (obviously all at 70 MHz). Why it does measure right alone and wrong with a coaxial "T" adapter and the dummy load in parallel?
Of course in real life I'm assuming a Vf=0.88 for the cellflex cable and checking measures with the analyzer.

What could be wrong?
Any hint is appreciated

The problem with soundbites and bumper stickers and tiny mantras is
that they appeal to the least common denominator.

Ideas and theories in nutshells belong in nutshells.

Probably not a whole lot, Harold. For that matter, there isn't a whole
lot in the newsgroup that is on topic,these days. Or if it is, it is
just a rehashed argument that has been going on for months now. Bleh.

Heck, even the original thread was off topic. So do you want us to go
back to the topic of the thread, of just quit posing on the topic.

Outlook should be able to allow you to filter us though. Might be a
better option for you.

Multipath isn't necessarily a big deal for DTV. The usual receiver has an adaptive equalizer that deals with it quite nicely, particularly if the multipath environment is stable. Throw in doppler and fast fading, and they're not so hot, but that's not a real issue for consumer residential use.

Hi Frank

At 70 MHz, when the open stub presents a reactance of -J21 across the 50 ohm "dummy load", the resultant R-Jx is a serious mismatch to the 50 ohm "A" line. Your Smith Chart calculations for the length of "A" may be incorrect. Try making "A"
about 1/10th lambda.

In simulation I am getting 86.8 degrees for the shunt stubs, and
62.4 degrees for the series coax between stubs. Seems about
the best compromise with results as follows:

65 to 75 MHz S11 < -10 db
65 to 75 MHz S21 > -1 db
88 to 90 MHz S21 < -16 db
90 to 116 MHz S21 < -20 db.

PS the single shunt stub of 86.8 degrees calculates to 11.7 - j 21 ohms,
when in parallel with a 50 ohm load (At 70 MHz).

Hi Frank

My calculations indicate that the length of "A" (50 ohm coax) should be close to 48.6 degrees between two identical open stubs with a 50 ohm termiantion on the 50 ohm line when I use your 11.7 -J21 impedance. So, my recommendation stands. Try a little shorter "A" if impedance match at 70 MHz is the objective.

Jerry

Sure. Even so, I didn't realize the truth was known _that_ far back. But
in the fifties, when I started smoking (briefly, thank goodness) we referred
to cigarettes as cancer sticks and coffin nails. Yet, lots of people
referred to the first Surgeon General's Report (1964?) as "groundbreaking."
Ah ... no!

I never was an expert on Smith Chart calculations, so I would adopt a
somewhat less precise (and definitely more suck-it-and-see) approach.

(1) Make 'A' a quarterwave at the centre of the FM band. This can be
done by temporarily connecting it as a simple shunt stub, and snipping
for a notch centred at around 98MHz.

(2) Make up stub 'B1' by temporarily connecting it as a simple shunt
stub, and snipping for a notch centred at around 93MHz.

Now, at 70MHz, the frequency response will be rolling off into the 93MHz notch, and the RLR will be getting rapidly worse. It will be a capacitive mismatch, so it can be corrected by adding shunt inductance in parallel with the stub. This can be an actual inductor, or a parallel stub with its end short circuited.

[The advantage of a stub is that you don't need additional screening. It can be tuned by pushing a shorting pin through the coax. The short can later be made permanent.]

So,

(3) Tune the shunt inductor/stub for best match and lowest through loss at 70MHz.

(4) Make up stub 'B2' by repeating (2) and (3), but for (say) 103MHz.

(5) Connect up the complete filter, with the 'matched' stubs separated by the quarterwave 'A'.

You should now have a filter with minimal loss and a good match at 70MHz, but with two deep notches at 93 and 103MHz. If you are happy with the results, finalize any temporary short circuits etc. If you are not happy, you can still make a few tweaks to the tuning. If all else fails, it costs virtually nothing to replace a bit of coax which is too short.

Interesting Ian, but of course you cheated by adding two extra components.
Just the same, it works exactly as you describe.

In my model I used inductors with a Q of 50. Step 3, above, works out
to 47.6 nH, and for stub "b" the shunt inductor is 62.5 nH. S21 from
88 to 108 MHz is << -20 db. S11 from 65 to 75 MHz is << - 20 dB.
The insertion loss is a nominal 0.4 db at 70 MHz. I used open ended stubs,

not that it makes any difference to the end result. The series stub is not very
critical, but response symmetry (S21 65 - 75, and S21 rejection 88 - 108) appears better. Note b1 = 94.5 degrees, and b2 85.7 degrees for my open ended stub model. Also the network is perfectly symmetrical; i.e. S11(f) = S22(f), and S21(f) = S12(f).

If anybody is interested I can provide JPEG copies of the response, and schematic, including a Smith chart plot.

73,

Frank

I would be interested of course, I tried to come up with an "all coax"
filter and with minimal parts because the thing must live under the
antenna and pass all the power on TX which can be a few hundred watts
one day, that's why I was using 1/2 inch cellflex (have also 7/8 inch
but no connectors for it).
I still don't get why a perfectly reasonable filter on the smith chart
turns out to be trash when realized, I'd really like to learn
something.

Hi Ian

I have had just enough experience with filter design to know that I dont
want to get involved with someone elses choice of which to use.
I am pretty sure that you are as "expert" with Smith Chart use as you care
to be. I make no claim to being a Smith Chart expert. But, I have alot
of experience using them.

I suspect that you know that impedances move along the lines (circles) of
constant R when pure reactance is added in series. And impedances move
along lines of constant conductance when reactance is added in shunt.
The chart with both lines of constant Resistance and constant Conductance
can be made by overlaying a second Smith Chart on the other with the line of
zero reactance aligned and the hi R flipped to overlay the low R of the
other chart.

Any impedance, with a REAL resistance will plot somewhere on the Smith
Chart. The outer boundrie of the Chart is marked in wavelengths. A line
drawn from the chart center thru the plotted impedance intersects the outer
boundry to identify a starting point. When that "load impedance " is seen

thru a length of lossles transmission line, it will plot somewhere on a circle whoes center is the chart center and which passes thru the plotted impedance.

In Frank's case, the where the load impedance is 11 -J21, the chart shows that 0.135 lambda of line length is required to move the load impedance to where it intersects the circle of constant Admittance, where the second stub moves the impedance to a good match.

Hi Frank

I am confident that you chose open ended stubs for good reason. Open
circuit stubs behave very unpredictably due to their sensitivity to their
environment. They radiate. Can you consider using longer stubs, and
making them shorted?

Yes, I considered that, however shorted stubs mean 1/2 wl at 98 MHz or so, and they become more than 1m long, making the filter not that easy to fit under the antenna, but who knows, maybe I'll be forced to abandon open stubs if nothing works.

Thanks for all inputs

Hi Francesco,

The point made about unpredictable open ends is found in their being
prone to common mode currents. You fix this through choking. Choking
can be achieved through coiling the stub. One, in a classical sense
(usually arrived at through examples oriented in microwave), does not
think of stubs coiled up; but coiling is a suitable, physical and
electrical solution. However, the open end is still prone to
environmental issues (moisture, bugs....). A shorted stub is
self-shielding, keeps out the environment, and coiling it up removes
the "too long" objection.

First, I apologize that I don't have time to look in detail at the
following ten postings in this thread; I did look over them quickly.

But two quick comments: First, I believe the "A" length should be about 44 electrical degrees at 70MHz to get a 50 ohm match at 70MHz. Second, if I were doing this and wanted to seriously attenuate 88-108MHz, I'd make a small L-C filter. At these frequencies, such a filter should be much more compact than a coax stub filter for some given performance. Of course, if there were specific frequencies I wanted to get rid of, I'd put zeros on them. Coaxial cavities are nice if you need very high Q around 100MHz, but stubs of even half-inch coax are not particularly high Q--expect Qu about 400 at 70MHz. A 47.7nH coil will give you your desired X=21 ohms at 70MHz, and you can get that inductance with about three turns of #10 AWG (2.5mm), spaced two wire diameters center to center, at about 9mm ID, and the Q will be just about the same as the coax (in obviously a much smaller space). But even better, a filter with max 1dB attenuation from 68-72MHz and min 55dB attenuation above 88Mhz (close to 100dB at 98MHz) can be built with four small coils and some C0G capacitors in a shielded volume perhaps 4cm x 4cm x 15cm. (Schematic is available...)

Cheers,
Tom

To be completely fair, they relied on cause and effect, which is to say
that they noticed a lot of people who smoked and chewed ended up with
these diseases.

But deep pockets kept tangling things up until testing came along that
not only showed that they caused the diseases, but the pathways, and
how, and in a 100 percent unambiguous way.

If we were to apply the same rationale and proof to say, falling out of
airplanes at 30 thousand feet, the argument would be " Well, can you
prove that the person died form the fall, or did they perhaps die of
fright on the way down? Can you testify with a certainty that is what
happened? As if the exact mechanism being indeterminate means the
activity should be promoted, when we all know that whatever the exact
cause of death, if you do fall out at that height, it ain't gonna be too
happy of an ending.

I gave the Qu about 400 number based on 1/2" ID of the outer
conductor, but I guess 1/2" CellFlex is actually about 0.33" ID of the
outer. Based on that, or based on the listed attenuation specs for
the line in this frequency range, I'd have to revise my Qu estimate
down to no more than 300.

Francesco, before you go, may I ask what is the purpose of the filter?
Is it to prevent the local FM stations interfering with reception? Or is
it to stop any unexpected transmitter spurious signals from being
transmitted in the FM band?

You are quite correct, as are the others comments in the same direction(s.)

Now, having been "burnt", in the past, by gov't, medicine, big money,
power and "the media", can you look around and see these exact same
tactics in use today? And, what percentage of the population is so
stupid they make no use of past history which recorded these lies and so
sadly demonstrated those lies ability to do much damage and death?

I will give you this--I feel it is a HIGH percentage!

"But you tell me
Over and over and over again, my friend
Ah, you doni¿½t believe
Wei¿½re on the eve
of destruction." -- Barry McGuire, Eve of Destruction.

It is to prevent desensing from strong local FM stations. Noise can go
up to S7 when beaming the local transmitters. An LC filter could be
easily made but that would need to be switched out when in TX (or made
to pass a few hundred watts), I just thougth a couple of stubs could
be easier to made. I think I was wrong.

Francesco, You can build a notch filter with two stubs, and get a good match, and rejection. The velocity factor of Cellflex 1/2" is 0.82, as per: http://www2.rfsworld.com/RFS_Edition4/pdfs/CELLFLEX_Foam_Cable_30-46.pdf The lengths of the shunt, open stubs, are reasonably critical within +/- 1cm.

I have used a Genesys optimization program with the physical parameters of the Cellflex coax. The open shunt stub lengths are 63 cm. The series stub is 41.3 cm. The insertion loss at 70 MHz is < 0.4 db. The return loss
at 70 MHz is < 20 db. Rejection over the whole FM band is > 20 db.

Using the Smith Chart to design a filter is tricky, since you are dealing with
multiple frequencies, and three variables.

Let me know if you would like to see my results, will be glad to e-mail them as JPEGs.

73,

Frank (VE6CB)

Right. The "noisy" devices -- motors, CFLs, dimmers, electronic ignition for furnaces -- are the problem for most users. Lightning is a consideration, but not all day and all night, like the appliances. A nice tall tower and a tight coax cable system will help keep out the domestic RFI, but the people who live in town are likely not going to have towers.

ok, with cut and try arrived at similar results, shunts are 64 cm and
series is 47 cm, the antenna analyzer is happy, I'm not so happy
because I don't understand where's my original error.

> Using the Smith Chart to design a filter is tricky, since you are dealing
> with
> multiple frequencies, and three variables.

well, yes, but actually the design started with the shorts at 98 MHz
which are easy, then the only unknown variable becomes the series stub
that gives a 50 ohm match at 70 MHz, I still don't get why the
matching section appear to be 3/8 wl on a smith chart and actually is
1/8 like if I inverted the sense of load/generator (yes, I worked with
admittances for shunt stubs).

>

No, you ARE correct. For non-experts like me, simple stub filters are
often very easy to make. This is especially true if you need to pass
only one frequency, and reject another. The one thing that you must do
at the 'pass' frequency is to tune out the unwanted reactance of the
rejection stub by adding a shunt inductor (where the 'stop' frequency is
on the HF side of the pass) or a shunt capacitor (where the 'stop'
frequency is on the LF side of the pass).

It helps if you should have (or have assess to) some test equipment
which shows you a swept frequency response and impedance match, but you
can also tune them using individual frequency measurements.

One great advantage of coax stub filters is that, unlike LC filters, you
do not need to screen each section. You can coil up the coax neatly, and
secure it with cable ties. However, it is sometimes a good idea to
ensure that the coax outers are completely 'RF dead' by bonding one to
another at several places (ie more than simply where one piece of coax
is connected to another). Of course, you can put the whole filter in a
metal box, and make sure that coax braid is connected to the box in
several places (and especially at the open end of the shunt stubs).

Of course, you can also make 'hybrid' filters which make use of the best features of LC circuits and stub circuits. I made such a filter for use with an FM CB radio which I had modified for use at the HF end of 10m. I found that I was still radiating (and receiving) some signal on the original CB band. The only practical way to eliminate this problem was to use an external filter which rejected 27 to 28MHz, but passed 29.3 to 29.7MHz. I did this by using two LC 'suck-blow' (stop-pass) filters in individual metal boxes, separated by a quarterwave of coax (coiled up, of course).

On the internet, there is quite a lot of information about coaxial stub filters (try a Google search). Anyway, may I wish you success, whatever filter you choose to use!

Hello...,

I was looking for LB Cebik's amod series (antenna modelling articles)
ranging from amod1.html to somewhere around amod137.html

Despite the fact that antennaX says that all of LB's articles are
freely accessable, I only find amod91 to amod114 available on their
website.

Anybody who does have the whole range of LB's antenna modelling
articles available ?

Thanks in advance,
Arie.

I've swapped the feed line over and its still the same.

When I put the antenna together I made sure all connections where good and the analyser gave a good match on the frequencies I want to use.

I did use some conductive grease for the first time on the antenna. Wonder if the grease is the problem or maybe this antenna just picks up a lot of background hiss.

Andy

I will try to rework the web page into several smaller pages.
I put the page together with Word 2007 as a single file web page. All
of the pictures as well as all of the control information is packed
into a single (large) file which must be read before the display can
start. Since everything is in one file it is easy for me to keep it
intact for editing but cumbersome to dwnload...

Good thing. Most standards based web browsers, such as Firefox, Safari
etc. do not support this format. I refuse to use Internet Exploder
(which seems to have a bunch of non-standard stuff it supports and only
it supports)

I am sorry to hear this! The ability to keep everything in a single
file greatly simplifies maintenance. I take care of several web sites
on a volunteer basis and keeping track of thngs is getting pretty
compicated. I will probably go back to Front Page for editing but not
uploading.

Francesco, I will be e-mailing my results for your interest. We seem to have arrived at the same conclusions.

I think I understand where you are confused. Initially, starting at the center of the Smith Chart, the shunt open stub moves down, along the constant conductance circle (0.2S). At 0.175 WL at 70 MHz (0.25 WL at 98 MHz) - 62 cm, the input impedance is 10 - j 20 ohms. Next; the series section of transmission line moves clockwise along the 10 ohm resistance circle. At 0.125 WL (70 MHz) - 44 cm, the impedance reaches 10 + j 20. The final shunt section then moves the impedance to the center of the Smith Chart along the 0.2 S circle.

73,

Frank (VE6CB)

Noise is RF the same as any other signal. The only exception would
be bad connections, etc that cause "locally generated" noise.
You need to find out if the source is received, or from a local
problem.
The SWR means little as far as receive. Any difference in level
due to SWR changes should be very small, and it would not effect
the s/n ratio if it did.
Does rotating the antenna vary the level of the noise? If so, the
noise is most likely received. You should be able to semi null
it out using the right direction if this was the case.
I doubt the element connections are the problem, or you would
see sudden spikes in the SWR when the connections flaked out.
What band is this on?
At this point just not enough info to tell what the deal is.
I could tell a lot more if I heard it. Can you record a sample
and post it somewhere?
Like I say, there should be little if any real difference in s/n
ratio if both antennas are pointed in the same direction.
Even if one had more gain in that direction, or was more
efficient overall, this would not effect the s/n ratio.
Noise and desired signals should increase in a linear
fashion.
IE: If antenna A receives the base noise level at S5, and the
desired signal is S8, and then you switch to antenna B
and the base noise is S7, and the desired signals are S9+,
they should still "sound" the same through the speaker.
The noise shouldn't seem any louder on antenna B, as
the desired signals and noise increase at an equal level.
This is why I say overall, it doesn't make much sense.
The reason I asked about the noise blanker is they
really degrade the dynamic range when strong signals
are present, and many overlook this while trying everything
else in the book. But.. A NB usually causes more of a
distorted audio sound, not static.

Do you get this same static when the band is "dead"?
That would tend to point to a pretty close noise source.
Either locally generated by bad connections, etc, or a
noise source nearby that is received normally.
But like I say, if you receive the noise, you should be
able to effect the level by turning the antenna.

The instruction manual for the antenna doesn't make it real obvious how the feedline attaches, but it looks to me like the antenna doesn't have a low DC resistance - like a loop would, for example. It's probably reasonable to expect this type of antenna to be noisier than a loop. I think Butternut attaches the feedline in a similar fashion on their HF6V, but puts an air core choke (from memory, 15-20 turns, 14 awg, approx 1" dia x 2.5" long) across the feedpoint. That may just be for noise because the antenna seems to have the same performance with, or without it. Perhaps you could try the same with the MA5V.

I think what the OP was getting at is the noise should be a lot louder with just the center conductor attached to the radio, and then get quieter when you thread the barrel on. If it doesn't do that, then there may be a connectivity problem somewhere.

As Microsoftisms go, this one is not among the worst. The format has a
standards track Internet RFC (RFC 2557) dating from 1999, and an open
Firefox bug dating from the same year. It is also supported by Opera.

However, the page doesn't open properly in Opera either. The web server
sends the browser the http header line 'Content-Type: text/plain',
telling the browser that the format is plain text.

So your web server isn't correctly configured for this format.

Nice thought. However, posting the URL like that is like asking for a
takedown notice.

I also downloaded a copy before the site was locked
down. Unfortunately, I missed the files Arie is asking for.

Downloading the mirror was certainly legal. Under Norwegian law, I am
allowed to give copies to others "within the private sphere", whatever
that may mean, but not to make it available to the public. I have no
idea what happens if a copy crosses an international border.

Its the thought that counts.
That zip file is just a collection of index pages which link to
content on WY6K's mirror site.... which no longer exists.

That's true, but there are surprisingly few actual IETF standards. A
lot of the stuff which is expected of a good net citizen is actually
just "standards track" or even lower status.

Hi Frank

When describing the path on the Smith Chart from the "load" Z to the "rig"
Z, you write "along the 10 ohm resistance circle". I would have refered
to that circle as the circle of constant VSWR.

I don't know if I am "reading" that sentence for the meaning you wish to imply ... or not.

However, most here in the USA put up a website to generate as much traffic to it as possible. The more traffic generated, the bigger the success realized. (i.e., I have never put up a site where mass traffic to it is viewed as a "problem.")

While some low bandwidth sites may use up their traffic allotment for the month (this encourages the successful to purchase more bandwidth), the next month the bandwidth is available, again. (on a free ISP, you may use up your bandwidth, but next month, it is available again.)

Your countries mileage may vary ... but then, in this country (USA), we cannot imagine paying a "Tele-tax", such as in England ...

Regards,
JS

Hi Frank

My reply was delayed because I had anticipated that someone might ask you for clarification on Smith Chart use. I was sure you'd clear up the confusion. I even thought I might learn something new. Smith Chart use is so valuable to my thinking that I just couldnt let this thread finish without checking in with you.

Hmm, unfortionally, no real usefull response.

I thougth that in the past L.B. Cebik's pages were some kind of
'freeware' and public accessable.

It's hard to understand for me that one is able to claim someone
others 'creation' and make money out of it.
I would have thougth that especially for someone like L.B. who did
such a tremendous job, writing all those articles for free and
publishing them for free, that all those who 'surrounded' him would
have honoured him and continue publishing his work without
restrictions...

Unfortionally this seems not possible anymore nowadays.
Too bad.

Arie.

Where are the days that people did things for free, just because they
enjoyed it...

They're still here. NGs are one proof. Every year, hundreds or thousands
of insightful posts in almost any group you can name -- all without any
thought of compensation.

A bit hard to tell from the pic... but it looks like an MCX connector (and
they are very popular on GPSs).

Source record: 23979

100 m W can 7 Km

according http://uk.youtube.com/watch?v=xNFg8l5tjDI

I draw conclusion from the movie at 0.22 second from the above movie

1000 m W = 1 W

1 W can reach 7KM * 10

5 W = 7KM * 10 * 5

= 350 KM the signal still cannot reach the AO 51 satellite which is
850 Km away from the earth.

to reach AO 51 the power required at least 12.5 W

7KM * 10 * 12.5
=875 KM

is my calculation correct?

raw transmitter power is only one factor, you have to also consider the antenna gain, receiver sensitivity for the different modulation used, bandwidth, and noise. The biggest factors in this case are probably the modulation type and noise. with ssb or even nbfm you are dealing with a much narrower band signal than 802.11 that hops all over a wide bandwidth. This lets the receiver pull the signal out better. Also the ssb or even nbfm is easier for the human ear to copy through noise, and cw is even better, but the access points have to deal with separating out the frequency hopping digital data from all the other digital data noise on the same frequencies... and if noise takes some of it out it is much less forgiving than the low data rate human ear and brain.

You have reached the wrong conclusion about the distance 100 mw can reach. That distance is just one persons expirment and also over earth and not direct line of sight. Also the type of equipment used is not very well designed for maximum distance. There is no real set distance that a given ammount of power can reach. It also depends on the antennas and receiver and several other factors. Knowing all factors involved the distance can be estimated very close.

Why buy either. There are plenty of plans for beams around. It is my
opinion that building one from scratch is not much more difficult that
putting one togetther from the box. In the process you will learn how
boom length, element spacing, numer of elements all come together to
give you a good antenna, If you can download the assembly manual you
will probably have enough detail for building your own.

Back in the 70s I belonged to a CB club. A group of us started
building antennas for ourselves and other club members. We purchased
our aluminum at an extrusion plant. By going through there reject pile
were were able to get the tubing for pennies on the pound. We placed
the tubing in a jig and was able to cut nearly all the pieces(even for
large booms) to length with one pass of a radial arm saw. Nearly all
that was left was to put the parts in a cardboard box with

instructions and a hardware list.

This was a great club with over a thousand members. We did not tolerate illegal or obnoxous operation. The penalty was expulsion from the club and you would be placed on the list where other members just wouldnt talk to you. On the other hand benifits of belonging to the club were considerable. Education Inexpensive antennas and equipment lots of help and fellowship and numerous family oriented events throughout the year. The group as a whole was a huge pool of talent for just about anything you could think of and we helped each in a lot more ways than just CB. A model for even the best ham clubs I have seen.

661. Re: MA5B background noise

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-25 14:42:14 UTC
From: Andy <dx90@blueyounder.co.uk>
Message-ID: <7Dlik.177$zA7.35@newsfe28.ams2>
Source record: 23985

The noise stays the same when I turn the beam.

I will try to get a recording done this weekend if I can.

I just pulled out the PL259, so just the canter pin on the PL259 on the
canter fed dipole was connected
and the noise increased with the signal and then dropped when the PL259 was
screwed back in. I had the same on the Cobwebb.

When I did this on the MA5B the 10, 12, 15 and 17 meter bands did the same ,
on 20 meters it was different. When I pulled out the PL259 so just the
canter pin of the PL259 was connected the noise dropped and with the PL259
screwed in
fully the noise went up. The opposite to what I thought would happen after
trying this out on my other antennas.

Sorry, but my previous comments pertained to the MA5V (vertical).

Having just assembled a TH-3, I can only suggest that perhaps you have
an open trap or two. Did you check the electrical continuity along each
of the elements after assembling them? What is the SWR on 20?

No.Bear in mind that signal strength goes as inverse square of distance.. Doubling the distance requires 4 times the power. Or conversely, 10 times the power only gives you about 3x the range (square root of 10)).

However, the initial assumptions for required power (100mW = 700m) is invalid.

For example Pioneer 10 radiated about 8 Watts at 2.2 GHz from well past the orbit of Saturn, and we detected it here on Earth (but we used a big 70m dish with a cryogenic receiver to do it). And it's not like it carried voice.. more like telemetry at 8 bits/second.

So, let's get back in the realm of possibility.

Since you're looking at AO51, that's an FM receiver on the bird. It's spec'd to require -125dBm on 2meters. The range to the satellite varies from 800km (satellite overhead) to 3000km (satellite on horizon).

On 2M uplink, the path loss due to distance is about -145 to -134 dB plus another 3 or 4 dB for ionosphere and polarization losses. Working backwards: -125dBm +140dB = about +25dBm (300mW) into a omnidirectional antenna should do it. In reality, you might want to use a 4-5 Watt transmitter and a 6 dB gain antenna to really get a good signal in there.

http://www.qsl.net/kb7ino/2_sat_calc.html has more info, as does http://www.amsat.org/amsat-new/echo/Echo_Linkbudget.php

665. Vertical problem

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-25 17:44:46 UTC
From: 826 <methinks@nospam.com>
Message-ID: <g6d3ebrft1@news.albasani.net>
Source record: 23989

Hi. Have a new Hustler 6 band vertical. Installed the radials and also buried 75 foot of RG213 coax between shack and antenna. I used a 6 foot peace of coax connected to adjust the antenna with a MFJ-259. Every band was tuned to the middle and SWR was lower than 1.7:1 at the edges. After the adjustments, I reconnected the buried coax to the antenna and on all bands everything had shift up by any where from 200 to 400 khz. Now the rig is seeing greater than 2:1 SWR.
Should I retune the antenna with the MFJ 259 in the shack?
Thanks Vern M0WQR

666. Bicycle frame as antenna?

We've been having trouble with bicycle thieves in my neighborhood. I'd like to set up a "bait-bike" that includes a low-power pulse beacon AM transmitter inside the frame and ***no visible*** antenna outside the frame. I'd like to have approximately 1-mile range. I've built a couple of Ramsey kits, but don't have much expertise.

- I'd appreciate any recommendations for a transmitter circuit.
- Will the frame perform as an adequate antenna?
- How about a dipole made from insulated wire taped to the exterior of the frame?

As a point of comparison: the Voyager space probes have transmitters
running at around 23 watts, and are capable of sending a useful
telemetry signal over a distance of 7 billion (!) miles.

Lots of antenna gain on the sending end (14-foot dish), lots of
antenna gain on the receiving end (100-foot dish), and a low data rate
(and hence a narrow signal bandwidth, minimizing the impact of noise).

Equally unlikely.

If you have built Ramsey kits for AM transmitters, you should be well
aware that they rarely transmit more than a block for the suggested,
large (relatively speaking, of course) antenna. Putting something
smaller, inside the frame is like trying to yell through a straw.

Look for an FM transmitter kit. The antenna can be the frame and a
wire wrapped around what looks like one of those kid's fiberglass
whips for a flag. The whip only has to be a meter long at most.

Hello,

When you mean "AM broadcast band" with AM, you will very likely not get it working. You will not be able to make a concealed efficient antenna and noise level is that high, that you will never receive the signal at one mile distance.

The antenna is the (most) difficult part. I would recommend you to go to VHF (as Richard suggested). You can use the bicycle frame as ground (counterpoise). You could insulate some metallic parts of the bicycle (Rack, Fender, mudguard) and use that as an antenna. Make sure that you don't compromise safety when modifying bicycles. The antenna impedance will be reasonable so you can probably use a simple matching network.

Because of the short(er) wavelength you can have some directivity in the receiving antenna also, this helps to trace your "bait". "Bait-bicycles" are frequently used by the Police.

When this is a non-commercial project, you may seek advice from the Radio Amateur Community (in fact you did via this posting). Also don't forget the legal aspects of radio frequency use.

Best regards,

Wim

Interestingly, the working on the above document ignores rx antenna gain in the uplink calcs, which may mislead the beginner.

The spreadsheet has the uplink 2m rx ant gain at 2dBi, and includes a somewhat unrealistic 3dB of tx line loss on the uplink. These compensating factors deliver somewhat similar outcomes.

The 2m uplink margin with a 5W tx is huge, something less than 1W might still be adequate for the proposed 6dBi antenna and say 1dB of line loss.

Owen

You would need an LC (inductance/capacitance) loading circuit to resonate the frame as a 1/2 wave "antenna" before it would even be possible to work (heck, I have never really thought about it before, but resonating it, the frame, at a full wavelength might even be better!)

I have actually heard of people, successfully, using a 1/2 radiator with no counterpoise--with good results. In your idea/plan, this might just be the best go ...

A mile range? That would require power which might be difficult to provide with batteries and for an extended length of time ... where would you hide those batteries? In the handlebars?

I concur, perhaps a cheap FM xmitter in the range of 88-108mc. The
frame should serve as a good 1/2 wave antenna for this frequency and the
plans for such an xmitter are readily available--a search of the net
will provide you with multiple options ...

826,
My first thought is that the feed line has become 'part' of the antenna and has changed the antenna's characteristics accordingly. My second though, if that 6 foot of feed line was connected directly to the antenna when measurements were taken, is that you being that close to the antenna changed it's characteristics.
So, what to do? How about doing that checking from the end of the feed line that will normally be used? Make any antenna adjustments accordingly. Don't want that feed line to be 'part' of the antenna? Well, how about using a feed line to do the checking that's of an appropriate length to sort of 'cancel' it's self out, to do the checking?
Doing all that checking will also give you some idea as to the accuracy of your measuring device, and the characteristic values of the feed lines, etc, sort of.
That's the 'long' version. The 'short' version is that you're probably doing something wrong, re-do it.
- 'Doc

Not much of an answer, huh?

Andy,
Just from those readings, I'd have to say the antenna seems to be
operating normally/correctly. Shaking things while doing that
continuity test is usually a fairly good idea, intermittents, although
shaking the antenna isn't going to be very easy, sort of.
Not making both connections at the antenna terminal, only the
center pin, and changing the antenna's characteristics is normal.
Sort of going from a "tuned"/resonant antenna to a random length wire
kind of thing. (Receivers just aren't as 'picky' as transmitters,
have different requirements. Not a very good way of putting it, but
you get the idea?)
Don't give up, I'm interested in what happens.
- 'Doc

I have used some conductive grease for the first time on the beam. I've
never used grease before, do you think this might be the problem?

The other thing is, that the beam is at apex roof height and mounted on the
back of the house. I have no where else to try it out to see if this is a
problem.
The centre fed dipole has the element that connects to the centre pin of the
PL259 at house end and I don't suffer any noise hiss on that like I do on
the beam and the Cobwebb is at the bottom of the garden away from the house
and that has a very quite receive on it.

Hi Andy,

It is not the problem.

>The other thing is, that the beam is at apex roof height and mounted on the

>problem.

You are closer to noise in the home.

>The centre fed dipole has the element that connects to the centre pin of the
>PL259 at house end and I don't suffer any noise hiss on that like I do on
>the beam

However close one arm of the dipole is to the house, I will bet the
feedline is far, far away from the noise source.

>and the Cobwebb is at the bottom of the garden away from the house
>and that has a very quite receive on it.

Even further away from the noise source.

So far, no one has asked, and you haven't offered a comprehensive
meaning to this noise.... hiss is not remarkably unique at HF. For
comprehensive you do not state what frequencies it inhabits. OK, its
on the five bands, but is it everywhere else? Is it equally
strengthed?

A portable radio is a must for noise troubleshooting. If the S-9
noise covers 5 bands, this freestanding radio should hear it all. The
noise seems to be uniquely near the house, but can you wander the
neighborhood with a transistor radio and hear it other places? Can
you bring a transistor radio near the point the antenna is mounted and
hear the noise? If you hear it there, do you hear it in the garden?

On the other hand, if you cannot hear noise on a portable; then it is
not over-the-air, it is conducted noise. Severely corroded joints
could do that, but you already state this is a new(?), greased (that
is what the grease is for) joint antenna. Is the feedpoint choked?
(This is common advice.) Does the feedline pass near noise sources?
(Use your portable along the length of the line.)

How do you ground your shack? Some folks think that ground wires everywhere does the job - often that is the problem. Could that hiss be a hum? Poor antenna connections would be more like a sizzle. Descriptive terms are not often reliable symptom indicators.

You have a ground loop with your new installation.

Another solution could be APRS or something similar. There are separate transmitters small enough to fit in a 1.5 - 2.0" tube, encluding a battery. Antenna(s) in the seat, frame as the counterpoise? RF burns? Oh, yeah, sure. But who cares, right? All normal stipulations apply.

The frame itself may resonate on - or around - 2m (a fullwave, end to
end?). Maybe you can tap into it using a gamma-match.

Surprise!

It is turning out that coax isn't what you thought it was, is it?

Lots of folks think that coax is some miracle device that absolutely
contains all of the RF until the RF reaches (poetic license please) the
termination point. In truth, no such creature exists in any form of
transmission line.

What you are trying to do is to make the transmission line the worst
possible radiator and the antenna the best possible radiator. There are
gazillions of possibilities somewhere betwen those two potentials.

Run the full length of transmission line into your shack and then tune the
antenna based upon the data gathered in the shack. Yes, it is a PITA, but it
is the only way to do it, if you want the best tuning.

Every antenna system is just that, a system. It cannot be tuned piecemeal to
obtain the best end result. Welcome to the world of radio.

Oh, it isn't so bad once you get used to it. Now you have an excuse to invite a ham over to help you by reading the analyzer while you are outside making adjustments to the antenna.

Wait until you discover, if you haven't already, that adjusting one part of the antenna will cause you to readjust another part of the antenna, probably the one that you adjusted before the last part that you adjusted. Hang in there. It is doable. Good luck with your project.

Jack

I wouldn't think that homebuilding a repeater for GMRS service would be
legal. Isn't GMRS a CB subdivision? All equipment must be type accepted,
IIRC.

Admittedly, this is well out of my area of expertise (cheesesteaks-eating,
not making).

696. Lakeview 2 meter colinear as a base antenna: High SWR, radial length?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-27 06:29:35 UTC
From: Fieldops <wq1o.frank@gmail.com>
Message-ID: <f3df2203-d366-4c73-9695-602487f0e677@s50g2000hsb.googlegroups.com>
Source record: 23819

I have been putting together a 2m colinear in a mount bracket for portable base use. I cut three 19.5" radials and noticed that I cannot get the antenna under 2:1 swr. I adjusted the whip for 44" as instructed. Changing lengths did not get me under 2:1. It just changed the resonance point. Does the whip HAVE to be cut so too much does not go into the antenna? I adjusted it to the needed length, but did NOT cut the whip. I know that lakeview also makes this antenna in a base station configuration. Does anyone know what size radials Lakeview uses? Are the radials for this antenna primarily for decoupling? If anyone has experience with this antenna in this configuration, any ideas would be appreciated. Thanks!

697. An all-in-one solution for the HF Turnstile antennas

Message-ID: <2kZik.33111$Gb2.19933@newsfe29.ams2>
Source record: 23823

I have managed to make an mp3 up. The first 10 seconds is on the Cobwebb
followed by another 10 seconds on the MA5B beam pointed in there direction
and then back and forth every 10 seconds. The click is the antenna switch
clicking over.

It can be found here. http://www.hobby.pwp.blueyonder.co.uk/ma5b/ma5b4.mp3

If anyone needs to here a clearer one let me know, but it will be best after
the contest has finished.

Andy

This sounds to me as if the MA5B has a very high angle lobe which the
Cobwebb may not. More galactic noise in proportion to the wanted signal?

John

I forgot to mention before that the Cobwebb is 3 meters lower than the MA5B beam.
Here are some more recordings, as before 10 seconds from the Cobwebb followed by 10 seconds from the beam followed by the Cobwebb and then by the beam again and so on till the end of the recording. All recordings will be like this to save me explaining over each time. The beam is pointed in there direction. The noise and signal increases every time when switching to the beam.

Do you think the 2m/70cm collinear above the beam could cause this?

All of Cebik's articles were copyrighted and much of his work has
always been available only through AntennaX in book- or CD-form. No
real change there.

In my area, keeping a bicycle has always been difficult. Reporting a bicycle theft to the police provoked a response from them, similar to, "We probably won't find it."

Of course, stolen autos/motorcycles provoke a similar response. One is left with the opinion they have much better things to do ... like enforcing the laws which actually generate revenue for the city/county/state ...

The chain and lock I now carry in a bag on my bike weighs more than the bike itself ... some in my bike group first laughed. Now those who laughed, who still have a bike, carry something similar.

Heck, maybe I am fighting an uphill battle--perhaps "they" are right--and the wife and I don't need a bike. :-(

Anyway, I digress, I like your idea--but, what about a 1/2 pound of C4 under the seat, instead? <evil grin>

I even recognized the thief who stole my bicycle.
The police refused to do anything because the thief
told them that he had "borrowed" it and returned it
by leaving it on my porch that same night and he
didn't know what happened to it after that.

I am afraid, my response to "the cops", may have been along the lines:
"Oh YEAH! What was I ever thinking? That happens to me AND the
neighbors all the time!"

709. Does reactance of dipole depend on diameter ??

Newsgroup: rec.radio.amateur.antenna
Date: 2008-07-27 18:46:40 UTC
From: Dave <foo@coo.com>
Message-ID: <488cc291@212.67.96.135>
Source record: 23832
Cross-posted to: rec.radio.amateur.antenna,sci.electronics.design

I wish to know if the reactance of a dipole that is physically 0.5000 wavelengths in length depends on the diameter of the wire or not.

I know a dipole 0.5 wavelength long is not resonate, but inductive so you need to shorten it a few percent to bring it to resonance. I know the length at resonance depends on wire diameter.

But I'm interested if the reactance does very with wire diameter when the antenna is physically 0.5 wavelengths long, which means it will be somewhat inductive.

A book published by the ARRL by the late Dr. Laswon (W2PV)

Lawson J. L., ï¿½Yagi Antenna Designï¿½, (1986), The American Radio Relay League. ISBN 0-87259-041-0

has a table of reactance vs the ratio K (K=lambda/a, where a is the radius) for antennas of 0.45 and 0.50 wavelengths in length. I've reproduced that table below.

The first column (K) is lambda/a

The second column (X05) is the reactance of a dipole 0.5 wavelengths in length.

The third column X045 is the reactance for a dipole 0.45 wavelengths in length.

K	X05	X045
10	34.2	23.1
30	36.7	6.4
100	38.2	-14.1
300	39	-33.6
1000	39.6	-55.5
3000	40	-75.7
10000	40.4	-98.1
30000	40.6	-118.6
100000	40.8	-141.1
300000	41.0	-161.8
1000000	41.1	-184.4

What one notices is:

1) Reactance for 0.45 lambda is very sensitive to radius, varying by more than 200 Ohms as K changes from 10 (fat elements) to 1000000 (thin elements).

2) The value for a dipole 0.5 lambda in length changes much less (only 6 Ohms), but it *does* change.

3) For infinitely thin elements (K very large), the reactance of a dipole 0.5 lambda in length looks as though it is never going to go much above 41.2 Ohms. Certainly not as high as 42 Ohms.

Now I compare that to a professional book I have:

Balanis C. A., ï¿½Antenna Theory ï¿½ Analysis and Designï¿½, (1982), Harper and Row. ISBN 0-06-0404458-2

There is a formula in Balanis' book for reactance of a dipole of arbitrary radius and length, in terms of sine and cosine integrals. It's hard to write out, but the best I can do gives:

Define:

eta=120 Pi
k=2/lambda

reactance = (eta/(4*Pi)) (2 SinIntegral[k l] +
Cos[k l]*(2 SinIntegral[k l] - SinIntegral[2 k l]) -
Sin[k l]*(2 CosIntegral[k l] - CosIntegral[2 k l] -
CosIntegral[(2 k a^2)/l]));

where 'a' is the radius.

(It's in Mathematica notation)

What is interesting about that is that for a length of 0.5 lambda, the reactance does not depend on wavelength at all - it is fixed at 42.5445 Ohms. So two different books give two quite different results.

Numerically evaluating the above formula gives this data.

K X05 X045
----
10 42.5 35.7183
30 42.5 15.5269
100 42.5 -6.79382
300 42.5 -27.1632
1000 42.5 -49.4861
3000 42.5 -69.8555
10000 42.5 -92.1784
30000 42.5 -112.548
100000 42.5 -134.871
300000 42.5 -155.24
1000000 42.5 -177.563

Does anyone have any comments? Any idea if Balanis's work is more accurate? It is more up to date, but perhaps its an approximation and the amateur radio book is more accurate. (The ham book seems quite well researched, and is not full of the voodoo that appears in a lot of ham books).

BTW, I'm also looking for an exact formula for input resistance of a dipole of arbitrary length. I know is 73.13 Ohms when 0.5 wavelengths long, but I'm not sure exactly how much it varies when the length changes (I believe it is not a lot).

k = 2 Pi / lambda,

not 2 / lambda.

You can possibly see that when the length is 0.5 lambda, the sine term
in there is always zero, so the radius 'a' has no effect on the reactance.

> What is interesting about that is that for a length of 0.5 lambda, the
> reactance does not depend on wavelength at all - it is fixed at 42.5445

Sorry, I mean the reactance does not depend on radius when the dipole is
0.5 wavelengths in length.

>Should I retune the antenna with the MFJ 259 in the shack?
>Thanks Vern M0WQR

I have a 5BTV with buried radials. Works and tunes like crap without the radials. Tune the antenna with the 259 connected to it with the shortest piece of coax you can work with, like 1 foot. If you're a purist - which I advise - lie down so you're as much out of the antenna field as possible when taking readings. Or back way off and read with binoculars. (Just don't let your body affect the antenna tuning.) When that's done, coil the main coax or use a common mode choke where the coax connects to the antenna to prevent the coax shield from acting like a radial. Forget that nonsense of adjusting SWR by adjusting coax length unless you're prepared to use a different length for every band.

The MFJ 259 reads SWR with respect to it's own 50-ohm nominal impedance so if you can adjust to a very low SWR (and you can with a 5BTV or 6BTV), it should read the same at the radio end of a longer 50-ohm coax.

This is the formulation by S.A. Schelkunoff, which is one of many approximations to the general problem of finding the reactance of a simple cylindrical dipole of arbitrary length and diameter. The general problem was attacked for decades by some very skilled mathematicians and engineers including R.W.P. King, David Middleton, Charles Harrison, G.H. Brown, D. D. King, F. G. Blake, M.C. Gray, and others. You'll find their works scattered about the IRE (now IEEE), British IEE, and various physics journals. The problem can't be solved in closed form, so all these people proposed various approximations, some of which work better in some situations and others in others. A good overview can be found in "The Thin Cylindrical Antenna: A Comparison of Theories, by David Middleton and Rolond King, in _J. of Applied Physics_, Vol. 17, April 1946.

As I mentioned above, some approximations are better in some circumstances (e.g., dipoles of moderate diameter near a half wave in length) and some in others (e.g. fat dipoles or ones near multiples of a half wave in length). I don't know which is better for your particular question. The easy way to find out is to get one of the readily available antenna modeling programs, any of which is capable of calculating the answer to very high accuracy, and compare this correct answer with the various approximations you find published.

> BTW, I'm also looking for an exact formula for input resistance of a

> changes (I believe it is not a lot).

There is no exact formula for that, either. Calculating an exact answer requires knowledge of the current distribution, which is a function of wire diameter. Assuming a sinusoidal distribution gets you very close for thin dipoles, but it's not exact. You'll find calculations based on this assumption in just about any antenna text such as Balanis or Kraus. But again, you can get extremely accurate results from readily available antenna modeling programs.

Hi Dave,

Yes, it does.

You are working with source material with conflicting agendas. One is simply interested in what is called a dipole for the sake of field studies and the characteristics of that dipole are a good first order approximation. This means thin-wire by and large. The other source is examining the antenna itself (or so it seems by both accounts).

The fatter the wire, the lower the inductance. Naturally the reactance must follow. The fatter the wire, the more wavelength it encompasses for a given length, hence the length can be shorter for resonance. This shorthand hardly matters for conventional wire antennas as "fat" is in the extreme, and wire is hardly the proper nomenclature when we get into these gross dimensions.

Approximations of "fat" come with cage structures that attempt to mimic a solid of revolution.

If you want to find the author who developed the first principles of thin vs. fat, that is Dr. Sergei Alexander Schelkunoff (with Friis).

In what has been decried in this forum as the failed metaphor of an antenna as transmission line, the antenna formulas from Schelkunoff were derived from (beat) a transmission line, albeit a special one.

To attempt to draw parallels between transmission lines and antennas is fraught with failures, true. Specifically, the traditional dipole in its thin-wire implementation has no linear Impedance relationship along its length. The wire separation is always growing with distance from the feed point and thus the Z varies with distance. This failure was anticipated by Schelkunoff, and folded into field theory through using conic sections for the dipole arms. Hence the biconical dipole, the conical monopole, and the discone. The transmission line analogy survives through this legacy.

All formulas that you have probably recited are the degenerative forms for his based on the conic sections.

Now as to that degeneration of the conic section into "thick" wire to "thin" wire. The conic section is certainly thick at the distal end,

no doubt there. It is also thin at the feed point. The advantage is lowered capacitance bridging the feedpoint compared to that if the thickness were constant from the distal end - for a given thickness/length/resonance. Also the conic sections most nearly approach the shape of the emerging wave's initial spherical front.

Well, the long and short of it is to seek:

First, as you point out one book is using an approximation where the
other may be using calculated data. I believe the approximations start
by assuming a perfectly sinusoidal current distribution, which may not

be entirely correct, but does make the math easier. The ham radio book would be more likely to use output from an antenna modeler, since antennas are an area where theory gets damn complicated damn quick, but the modelers can do a pretty good job if you treat them right.

Second, check to see if they're both using the same equivalent circuit -- if one is looking at parallel equivalent reactance and the other serial, that would account for the difference.

Third, check to see if the ham book is giving you figures for a dipole way out in free space, or one that's mounted some known wavelength above some known ground, or that has some real resistivity in the wire, or some other 'real world' assumption that a pure theory book may not bother with.

Hi, Thanks for all your input. Hustler recommended using 5-6 foot of coax in there manual. This I did follow and the antenna tuned very nice. When I connected the 75 ft buried coax it threw me because the resonance frequency on each band went higher. I do not have a balun at the base of the antenna. I thought that after connecting the buried coax the frequency would go down because of the capacitance of the longer coax. After rethinking this I can see that adding a balun may help. Thanks for your help and will let you know how things turn out.

I'm not sure if the stuff in Lawsons book might be experimentally
measured. It references some stuff by Uda et al, but it was published in
a Tokyo University book - not exactly easy to trace, and I very much
doubt in English.

This is just one more example of an anomaly which reminds one of "The Emperor's New Clothes--Hans Christian Anderson."

That, for some strange reason, science cannot explain the relationship of conductor diameter to length in an ABSOLUTELY predictable manner smacks of "charlatanism." This is proof, in my humble opinion, that gross errors exist on a very basic level of our understanding/formulas/equations of RF and light ...

Einstein suspected "the answers" in a "small equation", perhaps as short as an inch and a half long which would encompass "the theory of everything." After pages of complex calculus/algerba/geometric equations--we end up little better than "a guess." :-(

Surely there are some out there knowledgeable of a "hand-job!" <grin>

Obviously, something is amiss, and until that is corrected we do better than "guess."

Regards,
JS

OK. I'm just a bit suspicious of computer programs some times, as
someone will have to choose an algorithm of some sort. But I assume you
are talking of something like NEC which breaks antennas into segments.

Balanis has it, but leaves it as an integral, without simplifying like
he does for the real part. Yet the formuals for hte real and imaginary
parts look very similar. I might be able to attack it with a computer
algebra system - maths never was my strongest subject.

I thought I'd looked in Krauss and not found it, but perhaps it is
there. I think there is a relatively new version of Kraus, but my copy
is quite old.

Hi Dave,

Your kick-off was already complex. A thick-wire can be monstrously thick and not do much about the overall length at the principle resonance:
http://home.comcast.net/~kb7qhc/antennas/verticals/Cage/cage.htm
It does have its advantages higher in frequency.

When we look at cage conicals, the flare angle of the conical shows interesting relationships - not so much at resonance as for the continuum of reactance and resistance. What I describe as optimal bears upon an arbitrary 50 Ohm relationship, but others might mine significance from the steeper skirts of the discone.

Quite possible. The influence of all large metallic objects in the near field of the antenna will have a marked effect on the polar diagram. Try removing the collinear to see what happens.

John

I suppose it's natural to be more suspicious of others' work than your own. I've personally found the opposite to often be more appropriate.

> . . .

But I assume you
> are talking of something like NEC which breaks antennas into segments.

Yes. You can find a good description of the method of moments in the second and later editions of Kraus. The fundamental equation can only be solved numerically, and the method of moments, used by NEC and MININEC, is an efficient way to do it.

Hallen's integral equation is exact, but it's not a formula, since you can't plug numbers into one side and get a result on the other. Nor can it be solved in closed form at all. That's why so much work was done on approximate solutions and on developing numerical solution methods. Feel free to write your own program to solve it, but such programs have

existed for decades and have been verified countless times as well as being highly optimized.

> I thought I'd looked in Krauss and not found it, but perhaps it is
> there. I think there is a relatively new version of Kraus, but my copy
> is quite old.

Getting the resistance is pretty straightforward once you assume the shape of the current distribution. Assume some arbitrary current at the feedpoint which, along with the assumed current distribution, gives you the field strength in any direction. With the impedance of free space, this directly gives the power density. Integrate the power density over all space to get the total radiated power. Then you know how much power is radiated per ampere of current at the feedpoint, from which you can calculate the feedpoint resistance.

This calculation is done in all editions of Kraus, I'm sure; I have only the first and second, but I can't imagine it was deleted in later ones. Be careful when reading Kraus, however. Unlike many authors, he uses a uniform, rather than triangular, current distribution for his short elemental dipole examples. This is equivalent to a very short dipole with huge end hats, not just a plain short dipole. The half wavelength and other dipoles in his text are conventional.

Funny, I've seen no one recommend addition of a 1:1 choke balun near the antenna feedpoint. If RF is flowing back down the shield of his feedline, that surely could cause some incorrect readings on SWR in the shack, wouldn't it?

About as well as it flows up the center conductor, possibly. You
don't think that just because the cable is buried that RF flow on the
shield conductor is prevented, do you?

I think your antenna system itself is probably normal for the
most part. I do hear some "whine" though on a couple of
them. Not sure what that is, could be puter/monitor related..
How is yours mounted? Flat horizontal? I had to look up a picture
to see what they are, and the one in the picture seemed to be
tilted. ? Maybe that was just to show up better in the picture..
As far as the static in the last one , it sounded like power line
noise for the most part. Either the antenna has a strong lobe
towards that noise source, or you have some noise around you
that is being piped up the shield. But almost sounded more
like it was received by the antenna to me. You should be
able to vary the level of the static, and maybe even find a
null of sorts if you turn the antenna. If not, I would look at a
possible ingress problem, and the noise coming from your
shack or house.
I checked the feed, and they seem to use a matching device,
feeding two elements. I assume they are probably feeding 10m
with a separate DE, or something along those lines.
I doubt this matching device deals with decoupling the feedline.
So the first thing I would do is make a choke out of coax.
You can use the feedline you have now, and just roll a
choke at the antenna end. 8 turns using a 6 inch diameter
coil. You can use tie wraps, tape, etc to secure the windings.
That should take care of most any ingress/common mode
problems, if you have any. At the least, should put a pretty
good dent anyway. If the noise is still strong with the choke,
it's probably normally received line noise, fence, etc in the
area. And other than turning the antenna, not much you
can do about that.
That you seem to have a normal match on all bands seems
to indicate to me that your elements, matching device, and
coax are all probably ok.
I strongly recommend adding the choke though, just to nip
the possibilities of noise ingress in the bud. Just one less
thing to worry about, and just that much less RF you will

have on your coax when transmitting.

Hi Ed,

I think Jonesy is fairly safe in his presumption. The classic work
performed by Brown, Lewis, and Epstein pretty conclusively reported
the nearly complete attenuation of direct driven RF currents in ground
radials at 3MHz.

75 feet of buried shield would seem to be quite snubbed by the
proximity of earth over much of the range of frequencies reliably
operated from a multi-band HF vertical.

Of course, adding a choke can't hurt.

Since you clearly know more about this stuff than me, do you know of the best freely available software for this which works under Unix? (I use Sun's Solaris for 99% of the things I do, including sending this message. I use Solaris on my laptop too, rather than Windows).

Hence I'm almost certainly looking for source code in either C, C++ or Fortran. Anything that works under Linux would almost certainly be able to be compiled for Solaris without too much effort.
I found this page:

http://www.si-list.net/swindex.html

which has some source. I downloaded one

http://www.si-list.net/NEC_Archives/necpp-1.1.1.tar.gz

It would not compile immediately on my Sun. gcc 4.3.1 complained about some ambiguous code. gcc 3.4.1 did not, so I got past that bit.

It then tries to link with the 'blas', 'atlas' and 'lapack_atlas' libraries, none of which my Sun has.

I then swapped to the Sun C/C++ and Fortran compilers, removed references to 'blas', 'atlas' and 'lapack_atlas' , and replaced them with 'sublibperf' which is the optimised library on Solaris. That worked ok, and I had an executable:

```
$ ./nec2++
usage: nec2++ [-i<input-file-name>] [-o<output-file-name>]
-g: print maximum gain to stdout.
-b: Perform NEC++ Benchmark.
-h: print this usage information and exit.
-v: print nec2++ version number and exit.
```

I've not done any more than that at this point, but proved it will compile on Solaris with little effort.

Anyway, if you have any recommendations for the best freely available Unix/Linux code, I would be interested.

Sorry, my knowledge doesn't extend to that of programs suitable for Unix
or Linux. The "Unofficial NEC archives" site is the best I know of for
various compilations. Hopefully some of the other readers can help you out.

My program, EZNEC, has been reported to run under Linux using some
versions of the wine Windows emulator, but not with others. You'll have
a lot more to choose from if you can emulate Windows.

What Richard neglected to specify is that the work of B, L, & E shows that there won't be significant current on the *outside* of the shield because of the burial. The current on the *inside* won't be affected.

What's unknown is whether there was significant current on the outside during the measurement with the shorter cable. If so, the cable and probably the person doing the measuring became part of the antenna and would therefore affect its impedance.

Thanks a lot. I'm just a bit anti-windows myself. Fed up with all the
hassle of viruses etc.

The CPUs in this machine are not even capable or running Windows, as
they are not AMD/Intel compatible.

I do of course have access to Windows machines, and might well check out
your code later. I assume analysing a simple dipole will be trivual and
not require a huge amount of work.

But you have helped me understand the differences in impedance between
the different sets of data I have seen, which was my main concern. For
the immediate future at least, I am not going to do any numerical

analysis, but I might well look at that for a later date.

You're welcome. Yes, I would be interested in hearing how it turns
out for you. Works well for me.

BTW, my coax lays on top of the ground. Shouldn't matter with the
choke at the feed point.

Hi,
Here is some more info. The depth of the coax is 6". Its length is 75 foot of RG-213. The ground here is below sea level (3 ft). It was reclaimed from salt water by wind driven pumps in the 14th and 15th century. The conductivity of the ground is great for antennas. But not sure about buried feed lines.
I tested the antenna with the MFP-259 and 6 ft of cable on the ground. Yes the first thing I checked was if the reading changed if I backed off from the instrument and antenna.
I have tried buried coax one other time with a 2m vertical and thought the coax was bad because it was used before. It also gave bad reading but can remember the details. Do remember running another peace of coax back to the shack overhead and everything was OK.
Now I wondering if it is something to do with the installation. The coax is new and inside of a garden hose for protection. I did check the hose to make sure it was dry before it was used.
I know that the antenna is adjusted correctly and have taken an FT-817 and SWR meter to the antenna and it also indicated good readings.
Now something tells me not to tune the antenna with the instruments locate in the shack because it will not be curing the problem. It will just hid it until I start running some power. Then I would think something would start to get hot in the field. Like the traps.
Because the antenna no longer wants my power because its no longer tuned to the ham bands.
Regards
Vern

I, like Richard C., would like to encourage you to the use of a 1:1 current-choke/balun, either of a toroid core of proper material--or even a ferrite rod, beads, etc. -- and installed at the antenna feed point or both ends of the coax (xmitter also) ...

I would have to install software and check out a couple of things. But, I suspect, and especially at ~28+ mhz, that capacitive load on the outer conductor can't help look like anything other than/near a direct short. Even the rf down the inside of the braid/shield must be tempted to that path if it nears or is less than ~50 ohms (well, some possible/noticeable effect/affect.)

The coax I have buried, I always encased in ~1 inch PVC--possibly an overkill ... but hey, it was cheap when I bought it--I ran the UNUN (unbalanced-to-unbalanced current balun), just don't remember if I had to, or not ...

Just my two cents worth--feel free to disregard if someone ventures better/more-accurate data or proofs ... but then, you already knew that. ;-)

One other thing comes to mind: When you measured the antenna through the short piece of coax, was the shield of the long buried piece connected to the antenna's ground system? If not, you might try that. It would act as an additional radial, which would have some affect on the antenna's impedance.

Hi Vern,

You DO want to tune the antenna with instruments located in the shack.
You are tuning an "antenna system" and the complete system should
appear to be resonate to both the instruments AND the transmitter.
More power (or less power) should have nothing to do with the state of
tune - unless you have an intermittent. If you have an intermittant,
this is a failure, not a mis-adjustment.

From other indications you have shared, your problem is a
comparatively subtle error, not a major failure.

Judging by the signal to noise ratio, it sounds like the beam is a
better antenna than the cobweb when it's pointed at the transmitting
station. You might be able to tell that more readily if you turned off
the AGC. You can even watch the AGC changing on the Windows Media
Player spectrum scope when you switch antennas.

Quieter antennas are usually quieter both ways.

Balanis is giving the usual closed form expression for self Z.. I think the original is from Schelkunoff or King.. I don't have my copy of Kraus in front of me so I can't check.

Perhaps Lawson is using a different approximation?

Some formulas make the assumption of a sinusoidal current distribution, others are more refined.

>

73.1 +j42.5 to be more accurate..

"exact" as in analytical expression with no error? Or good to less than a percent? Accounting for resistance of the element?

As a practical matter, I use NEC for this kind of thing (which does take into account resistance, etc.) You can set it up to zap out a table that you can then interpolate into, for instance.

However, there are a variety of formulas that one can use. I suggest taking a look at Orfanidis's book
http://www.ece.rutgers.edu/~orfanidi/ewa/

Chapter 16 is probably the one you want. Figure 16.3.1 for instance. As you noted, X varies a lot more slowly for fat elements (which is to be expected..). Chapter 22 is also quite handy. Equation 22.2.10 is the expression for Z11, which is an integration of F(z), given in 22.2.11. The author makes the point "In evaluating the self impedance of an antenna with a small radius, the integrand F(z) varies rapidly around z = 0. To maintain accuracy in the integration, we split the integration interval into three subintervals, as we mentioned in Sec. 21.10"

He has matlab procedures and functions for most of them.. imped.m is probably the one you want.

FORTRAN would be the language of choice (since that's what NEC was written *and validated* in.. one would be concerned about a C translation, although I'm sure there are C versions out there which have been validated)

> It then tries to link with the 'blas', 'atlas' and 'lapack_atlas'

There should be versions out there that don't link with the matrix math packages.

What you've got is probably as good as anything else, especially if you're just looking for a table of Z vs length and diameter.

Vern,

An oft asked question, and there are usually emphatic answers readily
proffered.

You might find my article at http://www.vk1od.net/VSWR/displacement.htm
relevant to understanding what goes on 'within' the transmission line,
and the 'Traps for players' heading offers reasons why behaviour that is
inconsistent with transmission line behaviour may be observed.

In your case, one of the things you appear to have done is the change the
thing that was measured. You adjusted the antenna with the shield of the
main feedline disconnected. This is discussed under the heading
'Disturbing the thing being measured'.

Owen

But, if the choke/balun/unun suggested is implemented, shouldn't one
expect the transmission lines influence to measurements be expected to
drop to near zero effect/affect?--i.e., re-routing/lengthening/etc. that
xmission line (coax), opposed to measurements taken?

Or, in effect, your measurement(s) with a 1 ft. length of xmission line
will remain very stable if that length were lengthened to one-hundred
feet?; Given that the choke/balun is of proper construction to offer
HIGH impedance to the freq(s) in question on the outer braid/shield?

I certain have grown to expect this ... have I just been lucky?

Regards,
JS

A circular polarized antenna for half the am band up to 30mhz? Hey, the last contact I seen with the space shuttle was on VHF! No one told me.

Hey, is that gold wire and a silver chassis on the balun/feed-point? Does it use a yet unseen/generally-unknown, special, platinum-ferrite material in that balun?

My gawd, this man could on to something! ;-)

Frankly, I don't know if I can pass on this, or not ... I'll just have to "PLONK" on this, awhile. <grin>

I'm pretty sure a ham CAN use a 5KW PA, as long as he limits the power out to the maximum allowed under our FCC rules. Its not the hardware that is not permited, its the actual power out that counts.

NEC-2 can be built for Linux, and binaries are available for some
distributions. I am sure NEC-4 also can, if you get a license.

However, I have seen strange results come out of NEC-2 on Debian
Linux. Looked like numerical instability, and could be caused by a
problem in the toolchain. I don't think these binaries are used much,
so they don't receive the amount of tender loving care that they
deserve.

I am fairly confident that is true, and running such a rig at an "idle" would certainly guarantee a looooooong lifetime for the finals! ... but, with lawyers, you never know.

Anyway, a paranoid ham can certainly keep one in the basement for "The Big One!"

But, my post which started this thread was rather cryptic in its' intent; and, in my haste I failed to make that intent obvious. I meant to show what can be accomplished with censorship and why it is a most diabolical and evil weapon. Especially since the censor can "load the dice." A bully, a biased media, a pseudo-government entity--such as the arrl, etc., when, in the background, attempts to influence the public, that publics' options and access to ideas, well, this has always managed to get my blood to heat.

One thing I like about the r.r.a.antenna news thread is that we have "nuts" here, and sometimes that is exactly what is needed to seed new ideas, designs, etc. Or, to go where no mind has gone before (or is that StarTrek? <grin>)

Someone, somewhere, quite possibly from this group, will go to bed one night, much like John Kanzius. That someone will awake during the night, perhaps, and end up constructing the "new antenna" from his wifes pie plates. It may "change things."

Well, at least I think that much more plausible then someone from r.r.a.m (hey, is that a pseudonym for arrl? <wink>) awaking and saving the world with their rig and moderated newsgroup! ;-)

All,

Is anyone having a non-fossil powered amateur radio or homemade receiver picnic? Has anyone prepared a handout pointing to web sites describing historical and current solar, wind, earth battery, hand-cracked generator, etc. use in amateur, homemade, and emergency radio communications? I'd like to hear about activities and sites with just radio power-source facts—not explicit political content.

Thank you,

Steven, KD7YTE

John Smith quoted someone:
> "A 5 KW amplifier is not lawful for use under Part 97."

Back in the 60's, a ham friend of mine ran a
surplus AM transmitter capable of 10KW output.
However, he never adjusted his input power to
more than the legal 1KW limit.

The rules stipulate how much power can be run. They do not stipulate
how much power could -possibly- be run. It's up to the user to stay
legal. Simple as that.
- 'Doc

All,

In searching the web I found a few photovoltaic (sun battery) radio projects. I like the modest scale of the last link's solar-powered radio.

http://www.hobbyprojects.com/P/Photovoltaic_Circuits.html

www.newsociety.com/titleimages/pv_ch1.pdf

www.humboldt.edu/~serc/papers/WHECJune02.pdf

Good point.

>> It then tries to link with the 'blas', 'atlas' and 'lapack_atlas'
>> libraries, none of which my Sun has.
>
> There should be versions out there that don't link with the matrix math
> packages.

The Sun library 'libsunperf' has all the functions of blas, atlas and
lapack_atlas (well at least alls those used by NEC). I simply needed to
link against that one library, rather than the other 3, and I soon had a
n executable. I've not used it yet, as I have more pressing things to do.

That sun library should be highly optimised for the UltraSPARC
processors in my workstation.

But, we here, in r.r.a.a, can "cheat" that quite legally! It is called
high gain antennas ... (or, ERP)

However, those get more difficult with "distance" (i.e, meters) ... and
age. :-((not to mention rules/regulations.)

It's probably the old "How can there be too many people when there are so many empty spaces"? Chestnut, used by some to imply that we have alot of room to expand. The answer is simple.

If the land is crowded, you can't grow the crops.

If the land is in the middle of the Sahara, you can't have many people living on it.

Same goes for Death Vally, Antarctica, The Canadian Arctic, jungles and on and on.

In our area, Many farmers have sold off prime agricultural land for housing development. After all, "someone else" will grow the food. Problem is, the someone else sold off his land too.

When the places that are inhospitible to life are taken out of the picture, it doesn't look quite so happy.

Recently, over in r.r.a.m, the following exchange took place between me
and another:

EXCERPT FROM MY POST:

"> These freqs, being opened up for the net, is a very exciting development
> >... I believe the opportunities and access provided will greatly expand
> >the availability to the net under adverse circumstances, and make
> >greater speeds available to those who were lacking the same ..."

HIS RESPONSE:

"I do believe that the thrust of this group is to further Amateur
Radio, not "the 'net".

Then there are those of us who are professionals in spectrum
regulatory management who believe that this is a harebrained idea
from the get-go that violates good professional practice."

My NSHPO." [Not So Humble Personal Opinion? -- by JS]

MY ANALYSIS OF THE ABOVE EXCHANGE:

This individual, apparently/obviously, has no real respect for the
Scientific Method (i.e., Scientific Thinking.) He would have the
citizens suffer the will(s) of "us who are professionals." <snicker>
(Is that like alcoholics, they are, when they say they are one? <grin>)

And, I feel I could easily make a 1:1 replacement of "regulatory
management" with "religious devotion/doctorine."

And, his use of, "... from the get-go that violates good professional
practice" simply restates his preference to a "religious devotion" to
"arrl doctorine" over any REAL use of the scientific methods/thinking.

The "Coup De Grace" of his "thrust" being "NSHPO", indications of a
rather large ego, and usually held by an ego-manic!

Anyway, this "mans'" complete ramblings can be read over in r.r.a.m ...
it is well worth your trouble--if you need a laugh today; they are, now,
a matter of public record. ;-)

JS

Your post is inspiring, and immediately brings a hypothetical question to mind:

If an amateur is near a QRP'er on a field-day, they both have made contact with the same ham, on the same freq/mode and within seconds of ones' QSO ending, the other began ... and the QRP'er did it with 5w the other ham with 100w ...

Is the 100w'er in violation of the law? <grin>

Or, and perhaps more importantly, do you know of any amateurs who would "turn him in?" Or, call for his license to be revoked? -- I mean other than those in r.r.a.m, apparently?

Or, who really enjoys contacts barely above the noise floor? Well, sometimes ...

ROFLOL!

What they are doing over there is a blatent attempt to keep bozos off
the bus! It should be viewed as an affront to all bozos, and you are
well within your rights to be good and mad about it.

Oh now, imagine that; why didn't we/I think of that! There are "other possibilities" to his intentions/actions/words!

However, the alternatives bode poorly of the mans motives, intellect, reading comprehension abilities, trustworthiness, fitness for public position, etc. -- pick one or more at your own/his risk ... perhaps "manipulator" would be a compromise one could seek?

If your appraisal of "their intentions/wishes" is correct, and you are a friend, would not it be appropriate to inform them they have failed?

Indeed, apparently, while "their" attention(s) were elsewhere, the bozos snuck on that bus and now guide that "vehicles" direction ... <frown>

But you do have a point! Their inability to recognize their plight and what has happened to them is rather strange; do you believe anyone is home? ... Or, you think it might be something in the water they are drinking? :-(

How about we propose some experiments in which we put up a tower, and
grow crops around it, to see if the radio waves promote the crop growth?

I'll try the experiment with Barley and hops.... ;^)

Like you, I'm just an observer in all this, but it appears that Phil Kane (the gentleman to whom "Mr. Smith" was lecturing) must have been referring to the practice of using a 5 KW amp at its rated output on the ham bands as being unlawful. You probably remember Phil from r.r.a.p. He made his living as a practicing communications attorney IIRC.

Jim, I can possibly help clarify the situation, at this point.

The "gentleman" who took, apparently/NSHPO, responsibility for the censorship was Paul Schleck/K3FU (none other than a major player in the arrl wannabe political league) ... and, in my NSHPO, was stepping up to assist a friend (aiding an accomplice would just be too harsh of language) ...

Well, I am not familiar with google groups; so, I posed the question to my son, who in turn, posed the question to a friend ...

Short answer is: "NewsProxy", possibly used in conjunction with "Hampster." (will give you "God-like powers on filtering.")

However, their long answer included the fact that it would be much easier to set up a real newsreader through a free news server ...

Sorry, best I could do ... I really didn't really understand all they were willing to explain ... you will excuse me for now wishing to ...

However, to the best of, even, their knowledge, there is "no easy way" to do what you want.

Or how about genetically engineering a tree to actually be an antenna tree?
Just for kicks, we could patch in some genes to apple, peach and pear trees
too, so it wouldn't be a total ecological loss.

Ought to be obvious: An HF radio can transmit on all parts of its design
bands. License class determines the legality (or not) of the band
segment(s) the licensee accesses. Most hams elect to be straight-shooters
in this regard. Power should be the same.

You're too modest, "John". I've included a couple of your quotes for
balance.

From rec.radio.cb
Dec. 19, 2006

When I go shopping in walmart, I use maxon 49mhz headsets to communicate
with the wife. I use 5 watt cobra chicken band sets when camping.

I use a 1KW (1.5kw pep) rig for casual world chat.

5KW is just when I get serious ...

JS

From rec.radio.cb
Dec. 20, 2006

Jim:

Whether you are impressed or not is no concern of mine. Trash CB'ers? Naaa mate! My amateur equip covers the cb band quite nicely, don't mind chatting up truckers at all!

I was just asking you all if you would be joining me on the ham freqs, now that the CW requirement in the USA is being dropped ...

Regards,
JS

From rec.radio.cb
May 26, 2005
If one is smart enough to call it an "amateur amplifier" don't they let it be sold? Certainly every cb'er in the world is smart enough to know an amateur linear can be used on 11 meters with very little modification... Also, check out pages on russian linears, they have 3.5KW rigs which are very affordable... a friend going/living in canada can possibly grab one for you easily too... there are many ways around any roadblock they can throw up--retired engineers routinely build linears in their garages for "beer money."

Warmest regards,
John

From rec.radio.cb
May 26, 2005

Here is a guy which can help you out, or you can at least get ideas from his page...

A good 4KW to 5KW russian tube in a homebrew linear is just the ticket, especially if you just "idle" the tube at a 3.5 KW input... last you a lifetime and all the power you will ever need... someone should set up a home business building them...

Warmest regards,
John

From rec.radio.amateur.misc
May 25, 2005

I have a single russian tube (two tube in push-pull driving it--in the amp) which is outputting approx. 4.5KW... can you imagine what the transistor (mosfet) amp which could match it would look like--or cost!!!!

Warmest regards,
John

I'm certain that you're honest as the day is long and would never consider running illegal power.

Why stop at 97.313? Try 97.315 and 97.317 as well.

Unless "John Smith" has a "certificated for use in the amateur service"
5 kW amp (highly unlikely that one could find such a critter) or
"constructed or modified" the 5 kW amp then it is not legal for amateur
use at any power setting.

No, friend Gene. It doesn't work that way.

You do not have to have type certification for legal operation in the amateur bands. You only have to have it if you SELL new amateur equipment in the USA.

Home made gear, or converted gear from other services, is completely legal in the USA. Always has been, hopefully always will be.

CB gear must be type certified for selling and for usage.

Again, amateurs are responsible for their RF emissions. The FCC could care less about the type of gear you are using. In fact, if brand new amateur gear that was compliant to type acceptance malfunctions and issues an out of spec emission, YOU as a duly licensed amateur radio operator are held

responsible. Not the manufacturer.

Like..

The front panel has been modified to add a placard indicating that operation at more than XXX plate current is not permitted when operating in amateur bands.

And that whole "offered for sale" kind of thing is a huge regulatory morass, with a lot of "guidance" from local FCC officials on what might or might not prompt more attention. It's one thing to have an obscure ham oriented website and sell widgets obviously intended only for hams.. another to have a big online-store and sell obviously commercial products with a "wink, wink" disclaimer about only selling to hams, when in actuality, anyone with a credit card can get it.

The FCC enforcement logs are full of things like folks are selling "experimenter" video transmitters, but doing no substantive validation of the buyer. Ditto the stores selling various and sundry CB equipment.

Gene:

Skeptical, confused ...

Perhaps I can help with this link:

http://www.assemblywizard.fr33webhost.com/

Those 8 x QB4/1100GA "JUGS" at ~5.6KV @ 1.6 AMPS, 200 Watts DRIVE,
OUTPUT = ~5KW

That is not max output, the amp could have an increase in PV and Drive
to a theortical max output of ~7KW ...

I have tapped down on the PV, drive and even the current to the
filaments which are at about 85-90% of specs ... this amp is not in
everyday use--but then, you already knew that.

My son now has the 5KW "factory made" russian amp I used to keep. At a
later date I may have him take some .jpg pictures and send them to me to
load up to the URL ...

Now, off to the doctor ...

Regards,
JS

You forgot to mention purchasing it from outside our borders, perhaps
Russia, for example.

You forgot purchasing the parts and constructing it yourself, again,
Russian parts/plans are the cheapest ... (my city has the furtherest
inland seaport, yanno ...)

Now, what am I forgetting?

Really, I have a doctors appt. at 11 am ... gotta go ... bbl

Ed,

Sorry you have such a problem with basic literacy.

I stand by exactly what I said.

An unmodified manufactured amp that is not "certificated" is not legal
for use in the US Amateur Service, regardless of where it was
manufactured. A constructed or modified amp is potentially legal if
operated within the output power rules.

Did you read something else?

Gene, It would depend on who you purchased your AMP from, and if it was NEW at the time of purchase. If it was not "NEW" at the time of your purchase, and you purchased it from another HAM, or another Ham owned it at some previous time, then it is waived under 47CFRPart97.315(b)4,& 5, and if you Modify your "NEW" Purchase, by drilling a hole somewhere in the AMP, to add it to YOUR Station (Modification) they it is waived under 47CFR97.315(b)3(ii), as long as you don't "Modify" more than one AMP per year, for your personal use. (47CFRPart97.315(a).

There might be some wiggle room here... the relevant regulation:
97.315(a) Any external RF power amplifier (see ï¿½ 2.815 of the FCC Rules) manufactured or imported for use at an amateur radio station must be certificated for use in the amateur service in accordance with subpart J of part 2 of the FCC Rules. No amplifier capable of operation below 144 MHz may be constructed or modified by a non-amateur service licensee without a grant of certification from the FCC.

OK.. parse it out..

"manufactured or imported for use at an amateur radio station" must

This means that it only applies for amplifiers intended for use at an amateur station. If one manufactured an amplifier for use, say, in a RF induction heating system, one wouldn't need to be certificated for that use. (one might need certification for other reasons...) See, e.g., http://www.manitousys.com/media/pb3_manual.pdf.. They have a photo of the back panel, and I don't see a FCC registration number there. (nor does manitou show up in the FCC databases for authorization or grantee)

But, it's pretty clear that if that amp has a switch on the front labeled, for instance, "80m band", then it has to be certificated for use in amateur service.

(and, it's mighty tough to get a "certification for amateur service" if it can do other things.

If one went to Amplifier Research (http://www.amplifiers.com/, for instance, one could buy a general purpose RF amplifier. That wouldn't be "manufactured or imported for use at an amateur station" so it wouldn't need to be "certificated foruse in the amateur service".

here's a nice little room heater for you

Bruce,

Yes, I understand that.

My initial comment was directed at the growing theme in the messages,
not specifically expressed by you, that amateurs could legally use *any*
transmitter as long as output power rules were not violated.

It ain't necessarily so.

A small nit.. "any transmitter" is allowed.. the rules in 97.315 apply ONLY to external RF power amplifiers, and the class of "forbidden amplifiers" is actually quite small (a subset of those intended for use at an amateur station)

And this is in keeping with the concept in the regulation of Amateur radio: allowing basically everything and exclude a small fraction; which is different than the whole rest of radio, where it's: exclude most things, and allow only specific things.

This guy's name, address, and telephone number are listed in the web registration database. All this fuss about what's legal and what isn't is purely academic considering the total lack of enforcement. The FCC is much too busy trying to bust the broadcasters for a few milliseconds of boob to bother with this sort of thing.

Anyone can own any piece of radio gear legally. Restrictions are on sales
and usage.

So, while it is not unlawful to own a 10kw AM transmitter, even by a CB
operator, or someone that doesn't operate radio at all, it IS
illegal/unlawful for a business to sell new equipment to those without legal
qualifications.

What about salvaged/junk transmitters? I don't know.

Much has changed over the years, but "presumed innocent until proven guilty"
still carries a little weight here and there.

And my point is that ANY amplifier is legal, as long as it is operated within the limits specified by the FCC for the particular amateur band and license class of the operator. No type acceptance is necessary at all. Am I missing something Gene?

Bear with me, please. I'm on a lot of medication these days and I make mistakes occasionally. Thank you.

Guilty as charged!

I was careless to say "transmitter".

Ed,

I don't think that is correct. I don't believe it is legal to use an unmodified DaveMade or other such beast in amateur service, at any power level. I think that is the point of 97.315. It is about more than just "operation" within the rules.

I realize there are a million ways to get around any potential limitations resulting from these loosely worded and rarely enforced regulations. However, if for some reason the FCC wanted to go after someone I doubt that amateur "modifications" such as adding a placard or drilling a hole would carry much weight.

I have taken down the beam and did a continuity test and re-checked that the beam is put together correct and all seems to be ok.
Interesting about is could be power line noise. There are some over heads street power cables close by that supplies power to the houses. Strange how its just the beam that is effected by this. I have had HF verticals up here before with no problem.
I have just laid my hands on a Timewave ANC-4. Using its own small antenna it can cut out 80% of the noise but also cuts down the received signal to less than being received on the Cobwebb. But at least its a good start in the right direction. There was no manual with it. Any ideas on how to get it working better would be appreciated.
I will let you all know how I get on.

We should all read 97.315 *in it's entirety*, and consider 97.315(b)(3),

(b) The requirement of paragraph (a) does not apply if one or more
of the following conditions are met:
(1) ...
(2) ...
(3) The amplifier is sold to an amateur radio operator or to a dealer,
the amplifier is purchased in used condition by a dealer,
or *the amplifier is sold to an amateur radio operator for use at that
operator's station*.

This (the emphasized) says to me that as an amateur licensee I can use
any amplifier as long as I observe amateur emission regulations.

Respectfully,
Galen, W8LNA

All of 97.315:

[Revised as of October 1, 2007]
From the U.S. Government Printing Office via GPO Access
[CITE: 47CFR97.315]
Sec. 97.315 Certification of external RF power amplifiers.

(a) Any external RF power amplifier (see Sec. 2.815 of the FCC
Rules) manufactured or imported for use at an amateur radio station must
be certificated for use in the amateur service in accordance with
subpart J of part 2 of the FCC Rules. No amplifier capable of operation
below 144 MHz may be constructed or modified by a non-amateur service
licensee without a grant of certification from the FCC.

(b) The requirement of paragraph (a) does not apply if one or more of the following conditions are met:
(1) The amplifier is constructed or modified by an amateur radio operator for use at an amateur station.
(2) The amplifier was manufactured before April 28, 1978, and has been issued a marketing waiver by the FCC, or the amplifier was purchased before April 28, 1978, by an amateur radio operator for use at that operator's station.
(3) The amplifier is sold to an amateur radio operator or to a dealer, the amplifier is purchased in used condition by a dealer, or the amplifier is sold to an amateur radio operator for use at that operator's station.
(c) Any external RF power amplifier appearing in the Commission's database as certificated for use in the amateur service may be marketed for use in the amateur service.

Common sense would dictate (but then, as you already know, that is rare
to find), if the amp was stable, harmonics suppressed to specs, etc. --
use it. (i.e., emission standards obeyed.)

DISCLAIMER:
Great care should be taken with any "broadband amp", as any "flaw" in
the xmitters output is only amplified, linearly/proportionally, to the
amps' gain, in the amps output!

ADDITIONAL DISCLAIMER:
BEWARE OF ATTORNEYS/LAWYERS and "HAREBRAINED BUREAUCRATS!"

Hi,
Sorry I didn't rely sooner. The weather hasn't been too good hear. This
morning I disconnected the coax from the shack and measured the antenna with
the six foot length of coax. It looked OK. I then connected just the shield
of the long coax going to the shack and still measuring with the short coax
it shifted just like measured before in the shack. I have then made up a
choke balun and installed it at the base of the antenna and it improved
everything by about 60%. I will now make another one for the shack end. I
think everything is under control now. Thanks to all for heading me in the
right direction.

OK, I think I got it now. The only things no longer allowed are:

1) Stealing an amp rather than buying it.

2) Direct sales from a manufacturer or importer to anyone other than an amateur or a dealer.

The dealer loophole means that 97.315 is a total waste of ink and paper.

73,
Gene

Usually the your Electrical Utility, will have a supervisor in the
Distribution Department, that is responsible for dealing with
interference issues. Some utilities are more responsive than others.
When I lived down in the Flatlands, (Seattle, WA) Seattle City Light
had a guy that regularly meet with the local Interference Committee
which also included an FCC Engineer, the local ARRL Section Mgr, and
just about all the Marine and LMR Service Shops. He was also a Ham,
and used the information, developed by the committee, to track down
broken and failing insulators thru out their Distribution System.
The one outfit we could NEVER get to join the committee, was the
Cable TV Franshisee, and they generated MOST of the complaints.
Now I live out in the bush, and generate ALL my own power, so I am
the Utility, and I have to find and fix all the LF/MF/HF Noise if I want
to hear better. I usually have an MF/HF noise floor of less that 1.5
S-Units on my Kenwood TS690. I can hear, way farther than I can Talk,
due to the local Noise at the Receiving Station, masking out my
transmissions. It is frustrating to hear folks on 75 Meters with
S-7 Signals, but they can't hear me, due to S-9 noise at their end.

The power pole ground wire didn't appear to be
broken, just radiating like crazy. I managed
it by transmitting on the vertical and receiving
on the dipole. In the process of A/B comparisons,
I discovered that the vertical was never better
than the dipole and usually worse. The EZNEC
comparisons are on my web page at:

http://www.w5dxp.com/dipvsver.htm

To be fair, since receiving was limited to East/
West QSOs, the Extended Zepp beat the socks off
the vertical.

Now, while I think No. 1, "Stealing an amp rather than buying it", is, quite obviously, illegal, why in the world should one be required to be an amateur to purchase ANY, SPECIFIC, piece/module/system of electronic equipment??? There 'ya go, that "want for common sense" crops up once again!

Could you, EXACTLY, explain the logic in that to me? I am waiting ...

Vern, whilst the choke made a difference, the fact that there remains a difference in the feedpoint impedance with the shield connected and disconnected, even when using the choke, indicates that there is some effects observable from common mode feed line current in your scenario.

If you want a measurement of the antenna as it would be used, measure it as it would be used... make sure the shield current path is as it would be used.

Well, hold on, just got in from a road trip to Sacto, CA, have had time
to "cool down."

I will exclude any mechanical/electrical/electronic/esoteric/etc.,
strategic/military/etc. equipment of importance from that question ...
amateur equipment is FREE of those restrictions, IMHO ...

I have never made any comment about what "should" be the law.

What appears is that 97.315 is now totally useless for any purpose. It is no longer necessary for any manufacturer or importer to get a certification for external RF amps as long as they sell such items only to amateurs (OK) or "dealers". I don't know if the FCC defines the term "dealer" or if there are any restrictions on what "dealers" may sell.

This section of the law was originally intended to minimize the number of high powered amps available for CB use. It now appears that the only requirement for legal sale of such amps is that they pass through a "dealer". Usage is another question, but how many multi-kW CBers would worry about that?

Gene;

Perhaps I have "had a bad day." Or, perhaps I was "too quick." Or,
perhaps my understanding was lacking, etc. ...

Well, I certainly see no reason that a CB'er exceeding 5w is NOT in
violation of the law.

But to your question, "... how many multi-kW CBers would worry about that?"

My answer:

Every damn one that is breaking that law! Either pay the fines, do the
time, or change that law! (or, "we" change it.)

I stand corrected, I did not have the "beef" with you, it seems, I had
imagined ... I crawl back to my hole ... I stand corrected ... please
accept my apologies.

Warm regards,
JS

rules to limit non-amateur use of transmitters and amps should be other places anyway so its probably just as well that part 97 doesn't really limit what a ham can use. we are, after all, the ones who have to pass the technical exams and follow relatively technical rules. So we should be able to use whatever we can operate within our allocated frequencies, modes and powers. As opposed to fixed channel, power limited, appliances that are the legal radios for other services.

Knowing the structure is important. Most TTs are flimsy without adding reinforcement. I added a mast and rotor for VHF+ ops. For HF, I have tended to stick with the mobile antenna and add a section of RG8 into the trailer via pass-through. For 40 and 80 I add a 25' length of wire from the tip to a nearby support and load up as an inverted L or put up a Multi band Fan dipole. I hate trap antennas. No-workie on MARS.

Have used a 4btv on FD from my trailer but used a cement block to stand the antenna in the clear and added some counterpoise wires (grounds are hard to find in the mountains). The tongue mount probably works but will need to be carefully tuned and will put RF in the shack.

The inverted L extension to the mobile antenna gave good performance with the least setup hassle.

A couple suggestios: Does your trailer have a ladder in the back? If so, consider fabricating a custom bracket, fastened to the ladder, and mount your vertical on that (off to the side so as not to impinge on use of the ladder). I used two heavy aluminum pieces u-bolted to the ladder about 4 feet apart to hold my vertical antenna support mast. I bonded the bottom of my ladder to the chassis underneath with wide tinned copper braid strap and it makes an excellent counterpoise for my HF vertical mounted on the ladder.

If the trailer has a square bumper on the rear, that is another possibility for locating a mounting bracket with readily available clamps.

If you can't do this, you might consider buying, of building a simple vertical support of a steel tube welded to a flat plate. Simply park the trailer tire on the flat plate, which will hold the antenna base very firmly in place.

Since you are going to install it when you set up and remove it when
you tear down why bother to put it on the trailer at all. You could
hang it from a tree limb or mount it on a stake in the ground then
roll out some ground wires.

On 40m, most run horiz. Horiz-to-horiz is always going to beat
horiz-to-vert.

Knowing you and your strong personality (at least from the news group) I
thought you might had been able to secure a fix from the power
companies' noise emissions. Was just wondering, and probably wouldn't
have helped with my problem anyway ...

Right now, I have an issue with a noise source I cannot even pinpoint
and is very broadband (and no, it is not BPL -- already ruled that out,
lol.) Noise is for blocks and remains fairly constant in strength.
This would lead me to think it was powerlines; however, the powerlines
are all underground! Which leads me to believe some noise IS on the
powerlines and the radiation is coming from the wiring in each
individual home/business. However, a scope, properly isolated and
hooked to my wiring doesn't give me a picture I can correlate to ... :-(

If it ain't one thing, it is another ... keeps life interesting, I guess.

Regards,
JS

That would certainly be true for ground-wave. But the
effect is minimized by polarization getting scrambled
through ionospheric reflection.

True, but isn't the horiz better suited for placing more signal in a skywave which is, generally, more useful? i.e., a high vertical can put a whopping skywave signal into Australia--but is better suited for ground wave in USA--while a horiz does an acceptable ground wave and skywave here in the USA, and the world, of course ... ? (and of course, there are exceptions) Etc. It seems that way for me, anyway ... verticals are my main choice from necessity ... however, thank God I dumped that "big property" at the top of the market for this smaller place! <grinning-ear-to-ear> I'd imagine, by the end of the year, or middle of next, I can buy back the old place for 1/3 to 1/4 of what I sold it for, IMHO we are just at the beginning of the "downhill run!" <having-a-heart-attack-from-sheer-joy!>

Life is good ...

Regards,
JS

848. Help me buy VHF/UHF television antenna? Can't decide!

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-02 19:01:18 UTC
From: me@privacy.net
Message-ID: <vmb99494agov50d3f0gbsml6keb21d3t60@4ax.com>
Source record: 23722

I'm in zip code 63401

This means that my local off air channels will revert
to high VHF next Feb..... channels 7 and 10.

Along with few channels that will stay on UHF mainly
PBS channel

Soooo..... I need a combo high VHF/UHF antenna

Compact would be nice for sure

I'm looking at these two diff antennas:

Channel Master 2016

http://www.summitsource.com/product_info.php?ref=1&products_id=7084

Or the Winegard HD 1080

http://www.summitsource.com/product_info.php?ref=1&products_id=7048

I'm gonna mount the antenna at the peak of my side of
the duplex I rent and the towers are all in same
direction and 20+ miles northeast of me. I will use a J
mast and mount like a satellite dish.

Which of these two antennas would YOU go for and why?
I'm undecided!!

Even at the cost of not working? Compact is NOT an attribute that attends both multi-channel and HDTV.

>Channel Master 2016
>http://www.summitsource.com/product_info.php?ref=1&products_id=7084

22 Active Electronic Antenna Elements indeed. -whew- They may be counting the mast and the transmission line too for all that brings you in gain. Speaking of which, it isn't actually obvious what gain is coming your way with either of these. The quotes are "by gosh and by golly" sort of claims.

>Or the Winegard HD 1080
>http://www.summitsource.com/product_info.php?ref=1&products_id=7048

two bays, imagine!

These might receive your signals just fine as 20 miles is not that far away if both your antenna and the transmitter's are high enough. The transmitters probably are, even if they aren't trying very hard. You are lucky they are all in the same vicinity.

>Which of these two antennas would YOU go for and why?
>I'm undecided!!

Neither on the basis of the ad copy. It says nothing factual that can be a basis of comparison with rabbit ears in the living room.

Wait until you have real signals to see how bad things are. Then put your rabbit ears on the peak of your roof (with a good transmission line, not the $10 crap). Write back after this with results of this test IF you don't see what you like.

When I left home for the first time in 1966, I was headed for Lackland AFB in San Antonio, TX. It was my first passenger jet experience and was a direct flight from Philadelphia (yeah, I'm that old). I was astounded at all of the open land beneath the plane and as far as I could see. All thoughts of over population left my mind for a few decades.

Now a days, I have a little better idea of how much Earth it takes to support just one average American living our current average life styles. It takes a lot of land to support one of us when you factor in all of the things that we consume. Me, I don't want to give up a single damned thing. So, the answer seems obvious to me. We must put a halt to our expanding population until our technology advances more and provides us with some solutions. Is this written in stone? Of course not. Would I restrict anyone else's ability to procreate, based upon my impression? No, not at all. But I think it would be nice if we could at least talk it over on the net and on TV without the religious folks becoming rabid and incensed (sp?). As though that could ever happen...8>)

definitely the HD, anything with HD in the name has to be higher definition
than anything else and that must be better than non-HD.

853. Telescopic aluminum question

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-02 23:38:58 UTC
From: Ed <Huckleberry_REMOVE_@bigvalley.net>
Message-ID: <Xns9AEEA95F934D1Huckleberrybigvalley@198.186.192.196>
Source record: 23727

I am considering putting up a ground mounted vertical antenna, based on using telescopic aluminum tubing such as is available from Texas Towers or DX Engineering. Tubing available ranges from .500 inch to 2.125" with corresponding increase in price as diameters increase.

My vertical should be limited to a maximum of 30 feet, but preferrably around 23 - 25 feet. I will feed it with an SGC coupler at the base and operate 80M - 10M.

My question: Using the 6' long aluminum pieces, what is the minimum diameter sizes I should start with to enable the antenna stand up to a 75mph wind UN-GUYED. Also, how much "overlap" should I use in the telescoping pieces?

I will consider alternative means of building the vertical, but I really wish it to be unguyed .

Any info or recommendations appreciated. TNX

95% plus of the transmitter or received energy is safely contained
between center conductor and shield. That is how the physics works
out. All of the feed line center conductor current is pretty well
matched by the same current in the shield. It is the closely coupled
concentric magnetic fields that make coax work so well.

Or, simply put, for ever action, an equal and opposite reaction occurs
... yes, basic physics ... however, what is in question--since the other
braid has and "inside" and an "outside", where does that equal opposite
reaction occur ...

Regard,
JS

Gawd, I am getting hasty in my old age ...

No electrical field can occur without a magnet field, no magnetic field can occur with out a corresponding electrical component, again, basic physics; you are attempting to say the magnetic component of the current on the outside of the braid is NOT SEEN by the center conductor ... that may be in error ... but, I would be willing to listen how tinned copper (the braid) is some sort of shield to magnetic fields ...

Regards,
JS

Here's one data point:

I've had four unguyed verticals about 32' high in my back yard for over 20 years. They've survived gusts of at least 75 mph in a couple of storms, but we've never had sustained winds of that level while they've been up. They're made from 6061-T6 aluminum, 1-1/4, 1-1/8, and 1 inch diameter. The pieces are 12 feet each, so the overlap is about 2 feet. For mounting, I drove an 8 foot chain-link fence line post 4 feet into the ground, then clamped the antenna to it with muffler clamps -- long U bolts. Some pieces of 1/4" wall PVC pipe sawed lengthwise are used for insulation.

A 30 foot antenna will have a high angle of radiation -- about 40 degrees above the horizon at maximum -- on 10 meters. A 23 foot antenna will have a high lobe on 10, but decent radiation at lower angles also. A few minutes with any antenna modeling program including the free EZNEC demo program from http://eznec.com and the Vert1 example file will give you a good idea of what to expect.

It's unfortunate that this isn't true. If it were, it would make our lives a lot easier. Anyone interested in learning more about this topic might take a look at http://eznec.com/Amateur/Articles/Baluns.pdf.

They seem to be counting each half of a log periodit element as a separate
element. Ditto for each side of a corner reflector.

That's the down side, Most places I go would preclude running ground
wires.

That's why I'm looking to tie something to the frame to give somewhat
of a good ground.

Thanks for that info, Roy. I will finally download that demo software
and try it within the next 24 hours. Also, I appreciate the comments on
the other. While I can't easily get 12 foot sections, I'm sure I'll do
ok with the 6 foot sections. Here on the Oregon Coast we get storms with
sustained winds exceeding 75MPH sometimes. I would lower any antenna if
NWS were to suggest such a storm was approaching, but I'd like to have
confidence with the antenna if some gusts reached that speed on rare
occasion.

The high takeoff for 75M would be fine as most of my work in that
band would be within the State of Oregon, anyway.

Doesn't aluminum corrode pretty fast at the coast? My parents lived in Yachats, and aluminum didn't hold up very well at all -- although I'm sure that some alloys would be better than others. At best, you'll have to make heroic efforts to avoid electrolytic corrosion. I'll bet Danny, K6MHE could add a lot to this.

Basic physics is fine, but it's possible to reach all sorts of invalid conclusions if misapplied.

The relevant language in part 97 is that the available power to the
final amplifier stage must not exceed 1 kW for armature use. Other
jurisdictions have their own rules.

For all you disinterested parties

http://edocket.access.gpo.gov/cfr_2007/octqtr/47cfr90.313.htm

[Code of Federal Regulations]
[Title 47, Volume 5]
[Revised as of October 1, 2007]
From the U.S. Government Printing Office via GPO Access
[CITE: 47CFR90.313]

[Page 390]

TITLE 47--TELECOMMUNICATION

CHAPTER I--FEDERAL COMMUNICATIONS COMMISSION (CONTINUED)

PART 90_PRIVATE LAND MOBILE RADIO SERVICES--Table of Contents

Subpart L_Authorization in the Band 470 512 MHz (UHF-TV Sharing)

Sec. 90.313 Frequency loading criteria.

(a) Except as provided for in paragraph (b) of this section, the
maximum channel loading on frequencies in the 470-512 MHz band is as
follows:
(1) 50 units for systems eligible in the Public Safety Pool (see
Sec. 90.20(a)).
(2) 90 units for systems eligible in the Industrial/Business Pool

(see Sec. 90.35(a)).
(b) If a licensee has exclusive use of a frequency, then the loading standards in paragraph (a) of this section, may be exceeded. If it is a shared channel, the loading standards can be exceeded upon submission of a signed statement by all those sharing the channel agreeing to the increase.
(c) A unit is defined as a mobile transmitter-receiver. Loading standards will be applied in terms of the number of units actually in use or to be placed in use within 8 months following authorization. A licensee will be required to show that an assigned frequency pair is at full capacity before it may be assigned a second or additional frequency pair. Channel capacity may be reached either by the requirements of a single licensee or by several users sharing a channel. Until a channel is loaded to capacity it will be available for assignment to other users in the same area. A frequency pair may be reassigned at distances 64 km. (40 mi.), 32 km. (20 mi.) for Channel 15, Chicago; Channel 20, Philadelphia; and Channel 17, Washington, or more from the location of base stations authorized on that pair without reference to loading at the point of original installation. Following authorization, the licensee shall notify the Commission either during or at the close of the 8 month period of the number of units in operation. In the Industrial Radio Services, if the base station facility is to be used by more than a single licensee, the frequency assigned to it will not be reassigned for use by another facility within 64 km. (40 mi.) or 32 km. (20 mi.) where applicable for a period of 12 months, Provided, That the facility is constructed within 90 days from the date of the first grant, meets the loading standards to at least 50 percent within 9 months, and meets all loading standards within 12 months.

[43 FR 54791, Nov. 22, 1978, as amended at 47 FR 36649, Aug. 23, 1982; 62 FR 18933, Apr. 17, 1997]

Ed,
I'm certainly no expert on wind loading, so don't take any of this as 'gospel'. Having said that, I've found that winds in the 75 mph range can tear up almost anything, even if it is guyed. That's from living in "Tornado-Alley" and seeing things laying on the ground that shouldn't be. I figure guying is at least a sort of good insurance thingy.
If you get a lot of salt water where you live, I'd also take a few precautions about treating the antenna in some way to help prevent that corrosion. No ideas about that since I don't have much salt water where I live. There has to be something that will help at any rate.
And lastly, your vertical at 20-30 feet tall just ain't gonna work super-well on the lower bands where it's not going to be sort of close to 1/4 wave length (mobile 80 meter antennas come to mind). If you are happy with that performance, then big deal, who cares, it works.
- 'Doc

(None of these thoughts are all that 'fantastic', mostly just 'what-if's and 'common sense'. Also probably included in that list of mistakes I've made before.)

Actually the 2016 has some advantages. Although the other will have higher UHF gain, it has no gain and no protection against multipath on the VHF frequencies. The 2016 will be flatter with a cleaner front to back pattern (although lower gain). If you have no hills or tall buildings and the source is on a single tower, then the other may be better.

Depending on your terrain. If there are hills or tall buildings you will want a sharper, higher gain antenna then add attenuators or tilt compensation to reduce the reflections. Saving $20 or $40 can wind up a waste of money.

As always, your mileage may vary due to terrain, location and ERP of the transmitters. The real answer is to look at what others are using and see what the picture is like. If they suck on Analog, you may have dropouts on DTV. Anyway, its all just commercial liberal commie brainwashing and propaganda. What channel has the Rifleman and Andy Griffith still?

a couple of points come to mind here. First, Your not going to get much
out of a 30 Ft Radiator tied to an SGC Autotuner, UNLESS you have a
REALLY LOW Impedance RF Ground for you Antenna System. Radiator is just
to short. It would be a lot better is it were 70 Ft tall.
Second, there are, what is Known in the Marine Radio Trades,
"Pre-corroded Aluminum Alloys" that already have an Aluminum Oxide
coating on the interior and exterior surfaces. Then the trick is, to
get a good Metal to Metal Bond between the joints of the separate
tubing pieces. Usually done with Threaded Bolts, in Drilled and Taped
holes, and coated with &#65533;, or other such conductive substance.

We live in a similar situation, about two miles from the south-west coast of Scotland. After a period of strong winds, everything is plastered with salt spray.

In the two years since I started putting up antennas, experience with corrosion has been varied. The cast aluminum housing of the Hy-Gain rotor has become very heavily corroded. Antennas have fared better, and the Optibeam is immaculate.

Least corroded , of course, of all are my fiberglass poles with insulated wire taped up the outside. If corrosion is a worry, you might consider one of the Spiderbeam poles, which are made in Germany and are much stronger than regular fishing poles:
<http://www.shop.dx-is.com/product.sc?categoryId=5&productId=11>

A friend put up an 80m 4-square at about the same time, and at a similar distance from the sea. He found that although the tubing was OK along most of its length, there was extensive internal corrosion at the joints, due to the custom-made couplers that had been machined from a different grade of alloy. They wouldn't have lasted through a third winter, so he is changing to 40ft Spiderbeam poles mounted on 2in metal poles.

This is basically what I had.

The length is adjusted to be resonant on 40M.

It worked fine on 80M through 30M, OK on 20M (compared to a real 20M
vertical) and goes downhill from there, though it is usable all the
way to 10M.

I later modified it by adding a base loading coil switched in and out
with a relay that made it resonant on 80M with the coil in.

It now works pretty well on 160M and tunes up on 80M a lot faster,
though there doesn't seem to be any performance difference.

20M and above were not effected.

It is in the middle of a watered grassy area with radials.

When I first put it up I thought I could get away with not using
radials since the ground is allways moist; wrong thought.

Yeah I'm kinda leaning towards the 2016. But can you
explain why the 1080 has no protection from multi-path?
Are you saying that the 2016 is far more "directional"
than the 1080?

>Depending on your terrain. If there are hills or tall buildings you will

I have a dual band glass mount antennas but did not get info to install. I have installed the antennas and it seems to work fine on 2m as far as SWR. However, 450 SWR is very high and I am not sure what the small stub is to do. Is it vert.,horiz.,up or down? I have NOT tried to tune with the cap in the box as the SWR on 2 m is OK and not sure if it has anything to do with 450.

I know you didn't ask about the radio performance of the proposed design.

Nevertheless...

It is challenging to achieve good efficiency from such an antenna (ground mounted unloaded vertical, earth system, impedance matching at the base) at less than about 17% of a wavelength in height. My article http://www.vk1od.net/multibandunloadedvertical/index.htm models an unloaded vertical of 10m (about 30') in height, and also considers a better configuration (13m).

The article may interest you because it questions whether a 30' vertical is a good antenna at 3.6MHz, or above 18MHz.

In any event, the bigger issue is what is under the ground rather than in the air.

Owen

My thanks to those who have responded so far. Much food for thought. Roy, I downloaded the demo program.... BUT.... I'm going to have to spend some time learning its operation... it appears to have a considerable learning curve, which I'm sure will be well worth the time.... when I get it.

Commets on salt water corrosion have been noted. I'm about 1/4 mile from the nearest salt water.... and down wind. My mobile RV vertical antenna has been parked here for about 3 months now and is already showing early signs of the corrosion.

My thoughts at the moment are I can either easily remove the aluminum elements and clean them every 6 months or so, OR perhaps I should use an insulated wire supported by a fibre glass support. I note someone mentioned the DX-IS poles out of Georgia. Although I swore I would stick to only the vertical I originally spoke of, the idea of a quality fibreglass mast does seem to have benefits for my location. If anyone else can recommend other sources, or their opinions of robust fibreglass masts, I'm receptive. Given the comments on projected poorer performance of a 30 foot vertical, I suppose I need consider one that is higher, but I have CC&R's, and while not enforced, I do not wish to draw attention to myself.

Thanks to all, so far.

Ed K7AAT

I presume by stub, you mean the single radial that comes as an
attachement to the feedpoint. First, it is probably anodized black -
scrape off the anodization. Second, twist the orientation for best
results. Third, run the feedline close to the chassis (sheet metal)
to decouple it.

My EZNEC models don't show much difference in radiator materials with
a diameter of of 1.5 inches. Why not steel TV masting?

It has been mentioned that 70 feet would be better but so would 140
feet! We all have some sort of limitations. The important thing is to
get a workable antenna up.

If a thirty foot radiator is what you can do that is it. Life is
simpler with a good antenna tuner (I love my SGC-237) and I am on the
air. I expect it would work well with a thirty foot wire as well.

The more important consideration is the ground issue. I bought 2000 feet of insulated wire on EBAY and it worked out to about 35 radials of up to 70 feet. They are stapled into the grass and hard to locate after a couple of years even though they are bright green.

I rarely use the vertical for anything other than 40-80 & 160 but it will load up to 10 meters for sure and probably the advertised 6 meters for the tuner.

You might find my primitive experiment interesting.....

How much flex do you want to allow? You can make it pretty small, if you don't mind it bending a LOT in the wind.

Are you constrained to aluminum? i.e. what about a 15-20 foot length of chainlink fence top rail (aka galvanized pipe) with a standard mobile whip on top. If you're worried about conductivity, run some copper wire or a stripe of copper tape up the side.

I agree, if we manage to survive that long. Which I do not find all that likely. Or at least if we do, our innate instincts will ensure that we are at nowhere near the technical level we are today. More likely our tendency to overpopulate, not plan ahead, and kill anyone who doesn't look or think as we do will probably leave the survivors to emulate a lifestyle more akin to the middle ages. There are even some nutters among us who don't have a problem with that.

The original languages, like our own version of English,
had numerous definitions of "earth". I can cover the
"entire earth" in my handful of earth with a pint of water.

At the time of that original tale, man had absolutely no
concept of a 8000 mile diameter "planet earth". "Earth"
was as far (and as flat) as one could see and I have seen
Texas floods, in my lifetime, where nothing but water
could be seen. :-) Heck, I have been sailing on Clear
Lake, out by NASA, when I couldn't see anything but
water in all directions.

891. Slot Array Antenna Narrow bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-04 18:49:12 UTC
From: Chris <CWShannon@gmail.com>
Message-ID: <7bfb8b84-6f5d-4ed1-8b9c-bfe986d675cf@f36g2000hsa.googlegroups.com>
Source record: 23664

I've been looking at a few satcom antennas for a project I'm working on. We were originally looking at parabolic dishes but have recently taken a look at slot arrays. A low profile solution is desirable which would lead to a small dish or a low (but very wide) slot array. Some of the people we've talked to have warned us that slot arrays are narrow bandwidth. I thought I understood this issue, but I'm beginning to doubt myself.

Suppose a slot array could transmit at Ka frequencies from 30 to 32 GHz at a bandwidth of 3%. If the center frequency of transmission is 31GHz a 3% bandwidth would be equal to 930MHz or 465MHz on each side of the center freq. This may be narrow to an antenna designer but this is more spectrum than we'd ever hope to get on the satellite anyway. I'm a little confused over why this is an "issue", which makes me think I have a misunderstanding of the terminology.

Can anyone clear this up for me?

I use aluminum, a lot ...

Silicone, oils/grease has assisted me quite a bit ... as you already know the weight to mass ratio makes ones favorable to this route of antenna construction (aluminum) ...

In my meanderings about scape yards, I find titanium is becoming MUCH more available ... it is well worth the few available dollars ... and, of course, depending on availability, this is much more more desirable ...

It is possible to construct a MUCH more efficient antenna than can be purchased -- in theses cases, you are simply NOT constrained by the "costs of manufacturing."

Hi Chris,

The best way to resolve this terminology problem is to ask the ones
with the objections - it was their term after all.

Barring that, they could be talking about directivity vs. frequency.

Either way, the enumeration of your required characteristics should
point out how useful any system would be as their own may aid or
conflict due to their own abilities to support your goal.

Well.. a parabolic reflector has exceedingly wide bandwidth, and,
furthermore, its beam direction and or focus doesn't change with frequency.

Arrays of dipoles (which is what a slot array is) are (relatively)
narrow band, and the boresight direction/sidelobes may change with
frequency. The mechanical tolerances may also be tighter.

That said, lots of people use flat slot arrays or printed dipole arrays..
See, e.g.,

Or one that is shorter and abandon 80m. A message you should take away is that a 6.5m unloaded vertical (~21') is about as short as will give good efficiency on 40m... given an adequate ground system and tuner at the feed point.

I have one in my truck and these antennas are tightly tunned for the amateur bands. On mine there is
a tiny set screw to fine tune the coupler. As you mentioned, it was almost dead on for 2m but off on
446 or 450 so I had to turn the screw and now it's fine.

The stub you mentioned is a counter poise for the stinger outside since there is no true metal ground
with these.

I have a telemetry system set up so I can have radio collars on
animals (wombats) which transmits to a directional Yagi 3 antenna and
through to a TR-5 Telonics receiver. I am getting activity data now
directional data.
The wombats are zoo animals so the range isn't far (about 100m) but my
problem is that their dens are made of concrete and seem to block too
much of the signal. This system was used previously with no problems
so I can't figure out why it isn't now. The antenna is mounted on the
roof of my office building. Would it help to place it vertically
instead of horizontally?
What else can I manually do to boost this signal? Otherwise what is
the easiest and cheapest ways to boost the signal. There are twelve
frequencies that I am getting but about 6 of them aren't great, The
frequencies operate about 151.000
Help!

Hi all,
The antenna is now working very well on all bands. After installing both
choke baluns at the antenna base and in the shack, the resonant points
measured from the shack end were the same as with the short coax at the
antenna without the longer coax shield connected. Everything is OK now. All
it needed was the two baluns.

Aghh, good old wombats!

I'd suggest that any adjustable gain isnt going to help much. I'd concentrate more on your statement "This system was used previously with no problems". Do you have a breakage somewhere? Are the troublesome systems on one receiver? (if you have more than one) Are you sharing the frequency with someone else and getting interference? Are there any other sources of interference that may be the problem?

I suggest that horizontally is the best orientation as the antennas on the animals are probably also horizontal.

In my situation I'd also tune the equipment for best output just in case the attached wombats have damaged them. You *could* put a preamp on the receiver but I think that will invite more problems than provide a viable solution

If you have a scanning receiver have a listen separately for each collar signal. If they are all there suspect the base anytenna/receiver as being faulty. You may also hear interference.

Hope this helps

Cheers Bob VK2YQA

Hello, Cecil, and not quite. I don't know what you mean by "keeping a man technically dead" but I've haven't seen any reports on 5000 people being fed with a couple of fish, two people who were quite dead brought back to life or a person who was blind from birth given the capability of sight. Or the silly notion that a human being could be killed and, with assistance from a "higher authority", return to earth in physical form. Of course a lot of folks find the very idea that these events could have happened, let alone a couple of millenia ago, is a bunch of crap. Still one must concede in spite of one's spiritual beliefs that given a sufficient level of technology, one can indeed perform miraculous feats. Perhaps we will be able to do (some of) these things some day, but not today. Sincerely, 73s, and with apologies for injecting OT philosophy,

So it appears the statement is true and technically accurate but in my
case it simply isn't relevant.

All of what the respondent said, plus:

Was the coax leading to your base antenna weatherproofed using coax seal at the outside connector? If not, it is possible that rain water has contaminated the coax leading to your base radio. I've seen this type of problem cause folks to pull their hair out while trying to "fix" all of the remote units, when it was the base unit all the time.

What kind of connectors are used in your base system? If N-connectors it is unlikely that the above problem is the cause. However, it is also unlikely

that your system is using N-connectors because of price considerations.

A passive radiator system (antenna inside structure connected to an antenna outside of the structure the Wombats occupy connected by coax cable) could help. But I would find out why the system is not performing as it was before. As the respondent indicated, it could be something as simple as Tx detuning or increased traffic on the frequencies that you are using.

Most likely your problem has already been covered here, but when was the last time the batteries were changed in the Wombat collars? Signals will go down as batteries fade. How the heck do you change the batteries on those Wombat collars, anyway? :^)

I don't know about all that, I would look closer ... they are implanting stem cells in the retina and restoring sight and all that now ... I would at least do a complete search of the web first ...

However, you are quite correct "some people" do have some strange, quaint and bizarre beliefs ... for example: the belief I can take a handful of wood, glass, metal and plastic, toss 'em into a mud puddle and come back a couple of million years later and start digging up microwaves, cell phones, televisions, etc. (it is called, "evolution!")

Yep, you just can never tell what some people can be caused to believe!

Your path sounds very similar to mine. At first, unless the plans/specs called for a balun/choke, I ignored the need. Now I use one, or more, no matter what ... I picked up that knowledge here. At first, the loss of the balun/choke made me hesitant--I no longer worry about those trivial matters. :-)

Yep..

But check the tolerances on your slot array, particularly if you're
operating over a wide temperature range. Aluminum CTE is about 21
ppm/degree C, so over a 100 degree span, that's 0.2%. Probably not a
big deal for the spacing, but the slot size changing will change the
phase, etc. 0.2% isn't much, but you ARE talking about an antenna with
3% BW...

> explain why the 1080 has no protection from multi-path?
> Are you saying that the 2016 is far more "directional"
> than the 1080?

While the 1080 UHF is fairly sharp with some potential gain, the VHF elements seem to be little more than "rabbit ears" - In fact it is a swept dipole, so will be bi-directional and easily pick up reflections from behind and around you.. Sweeping the elements has the effect of allowing the elements to be better matched at odd multiples. The 2016 will have a broad front lobe (less directional) have good bandwidth, and signals from behind will be blockedfor UHF and VHF. It's drawback will be ice and wind loading. Still I would have really liked a 1080 with a few (like 2 or 3) more dipoles out behind for a better protection against reflections . I scratch my head to see a 15 db corner reflector UHF and 0db VHF dipole together. As if the VHF were so strong it was an afterthought. I have a wee bit more than that (same UHF but with 7 VHF dipoles) with some elevation looking at a mountain site about 75 miles away. My elevation just barely allows the signal to clear a pass 10 miles away and I have perfect Anolog reception while neighbors who are one stop closer struggle for signal.

In fact, I have used the antenna for 2m SSB with 10 watts.

Don't forget about good quality RG-6 for your feedline, and keep it as short as possible (but it is better to get the antenna higher to clear the next door building). This is more critical for UHF stations (perhaps why 1080 went that way).

> Yes I do have on bi brick two story building right in
> front of me in direction antenna must be pointed.
> <sigh>

That is a complication but not if your antenna can just see across the roof of the other building, then it can actually help. If the main signal source is reduced, reflections will be more pronounced. The problem with digital, all you have is a bar graph. Reception problems are totally masked. The reception problems that degrade Analog still degrade Digital, you just can't see it. I have seen situations where there is lots of signal on the bar graph, but the picture still breaks up because of distortion of the signal. So while Analog is still there, get your antenna aligned and locked down and hope no one builds another building.

Sometiimes pointing the antenna at a tall building or mountain will give a better signal because all stations are bouncing from that building..

If you can stand on your roof with binocculars and see the broadcasting site, and there are no 12-100 story buildings or mountains around, put your antenna there and be done with it. Keep in mind that if you find yourself running 75 feet of coax, it would be like putting up an $80 antenna just to shorten the coax to 35 feet.

What the bending of elements does is to align the lobes broadside at the frequencies at which the elements are approximately 3/2 wavelengths long (that is, at about three times the fundamental half wavelength frequency). Without bending, a 3/2 wave element has lobes which aren't broadside. Bending it brings these to point broadside, resulting in a an approximately bidirectional pattern. It's the shortest "vee beam" type antenna, which extends this idea by decreasing the angle to maintain alignment as the dipoles get longer.

The bending used in TV antennas has little effect on the impedance match.

Roy Lewallen, W7EL

Hi Chris

What directivity is required from this antenna?
Whats the limit of the budget available for the development of the design
of the slot array?

> Can anyone clear this up for me?

One of the things that occurs to me is that it can make a big
difference just how you feed the array. This is something I've
pondered with respect to linear arrays of dipoles at lower
frequencies. If I feed the array from one end and depend on the
length of transmission medium between the feedpoints, e.g. one
wavelength between each radiator so they're fed in-phase, the phasing
will change linearly with frequency. This is hardly noticeable if the
array is short and therefore has low gain; but if it's long so the
beamwidth is, say, 10 degrees, then a 3% change in frequency (.03*360
degrees) will tilt the pattern by about one beamwidth. In a waveguide-
fed system where the propagation velocity depends significantly on
frequency I suppose things could be even worse.

But an alternate way to feed such an array is with a tree of splitters
so that the propagation from the input port to each radiator is the
same time delay. In that case, the radiators will stay in phase and
yield a high gain over a considerable bandwidth. In such a case, you
do still have to account for the fact that the mutual impedance among
the antennas will cause the elements at different points along the
array to represent different loads to the transmission tree "leaves"
and therefore cause different phase shifts, but that's something you
can account for.

I recall once reading about a radar antenna that used a "geodesic
lens" to give equal time delay from the feedpoint to each radiating
element; it was basically a fan-shaped waveguide with a wrinkle in it,

deepest at the middle and flat on the outer edges, which caused the central transmission path to be the same electrical length as the outer paths (and all the others).

Cheers,
Tom

Thanks guys for your advice. The collars are a mix of new and old but it seems to be more location that is determining whether they work. (eg. some of the wombat collars are good no matter where while some are bad only in the dens). They are all new except one. I can hear them all really well when I scan them one by one but when I use them together I have the receiver in data acqiusition mode (to store all of the data for later download) which doesn't allow me to adjust gain or tuning. I guess that is why I assumed it was maybe not enough gain. The antenna outside is connected to the receiver by a RG58 cable. It is only covered in electrical tape at the connection. It was rusty but I have changed that all and the signal is the same. I can check the missing data on my video cameras and see that it is always when they are in their dens.
I think you are all probably right. Perhaps the antenna or receiver was damaged when it was stored or moved.

Ed, that defines how you define the problem.

If the problem was different measurements, that was caused by disturbing the thing that was measured.

The different measurements hints another possible problem, common mode feedline current. The baluns have changed the effect of those, and probably differently at different frequencies.

But fundamentally, it is wiser to preserve the common mode current path (even if you reckon the baluns help to reduce it) when making the measurments.

The whole exercise demonstrates that the measurements from shack were valid, it was disconnecting the feedline and making measurements at the feedpoint that was invalid. (BTW, the measurements in the shack should be done with the shield path connected as normal.)

A good example of the limited thinking in the proposition that you can only make valid measurements at the feedpoint.

Owen

Ok thanks for that explanation! I am in fact a general
class ham but haven't operated for years....no equip
either. And am def not an antenna expert. So its nice
to get some "science" on why one antenna is better than
another when it comes to DTV! Thanks!

For sure! Matter of fact I see some good prices on
Philips RG6 at local Walmart

Now I just gotta find a J mount for a sat dish as that
is how I'm mounting the CM 2016 when I get one. I will
install on the SIDE of a roof peak.... the fascia....
just like you would a sat dish

Gotta figure some way to get up there tho as no ladders
big enough. Guess I can borrow one from a friend

Well you have sure opened my eyes up to the importance
of a DIRECTIONAL antenna when it comes to DTV!! I'm
lucky in that all stations locally are broadcast from
same towers in same location..... so only one direction
to worry abt. Again my zip is 63401

Seems like the more directional the antenna the better
as it will be "blind" to multi-path. Yes?

I'm a bit confused on your remark above.

Looks to me like the 1080 is perfectly flat antenna.
Where do you see any bending or sweeping of elements?

922. The Strange True Story of a Radio Station's Transmitter in New York State

In the 1920's a radio station in Schenectady, NY built a powerful transmitter. In those days before FCC regulations, not knowing just how big to make a transmitter in order for the signal to be received some distance away, the station set up to broadcast at 500,000 watts. It requires about one watt to be received four blocks away. A cell phone is three watts. This station broadcast at such tremendous power that they could be heard around the world. People in New York didn't even need radios. They could sometimes hear voices in their furnaces and coming off chain-link fences. Light bulbs lit up in people's houses even if they were switched off. - from www.clip-text.com

---

Can you imagine the cost of their electric bill?

I used to pick up AM radio stations in my head. The theory back then was that it was due to dental work acting as a rectifier, etc.

I could tell you exactly which song was playing and where they were at in the song. All one had to do was turn on a radio and I would be singing in sync with it. The really weird part was that all I could hear was the music and the time announcements.

This was in the late 50's and early 60's when I lived in Carneys Point, NJ. The radio station that I heard the best was WAMS (1380kc) in Wilmington, DE. The second best was WFIL in Philadelphia, PA. The latter I heard after WAMS went off the air for the day.

It would be even more informing if the "gain" attributed to it (not to
speak of lobe characteristics) were revealed through a link, as
certainly the vendor is wholly lacking in those substantives.

This is actually used deliberately to steer a beam by changing the
frequency. Consider a radar with a magnetron that can be tuned...

And for which phased array designers spend significant amount of time.
There are "sweet spots" that are easier than others, and if you have
lots and lots of elements, then the fact that edge elements have
different neighbors than all the ones in the middle might be ignored.
All depends on the sidelobe requirements, mostly.

>

There's about as many schemes for feeding a phased array as grains of
sand at the beach it seems.

Except that some receivers actually use the multipath signals to enhance
the overall SNR, by essentially delaying and recombining them in an
adaptive equalizer. So directivity, if it comes at the expense of gain,
might not be what you want.

I am looking at a 1080. It is being used in the computer room. All of the elements are in two, parallel planes that are each normal to earth. In other words, flat. On high-VHF (channel 12, here) there is little F/B ratio, but that has not been a problem. The chances of needing to reject a high-VHF station (at 180 degrees) on the same frequency is slim. The antenna is a stout, little, two-bay broadside array with reflector mostly effective on UHF.

I provided a detailed set of measurements in another message. 73, Mac N8TT

Do really believe that there was a transmitter in the 1920's that could deliver 500 kw?. The first station that could come up with that amount of power was in the 1930's,W8XO, the experimental station of Powell Crosley, that became WLW again when the experimental period was over. Are you aware of the technical difficulties that obtained in just getting that monster to work? General Electric and Westinghouse supplied most of the parts, the rest by RCA, and RCA was the company that strived and strived before it was workable at that power level. I once worked for Harold Vance, the RCA engineer in charge of the project. Certainly this didn't happen in the 1920's, and not in Schenectady. Somebody's been
feeding you horse hockey.

Lucille Ball picked up radio transmissions during the WWII. There was a German spy network working close to her home at the time. Apparently she had some dental work done and when she laid her arm against the metal bedpost at night she picked up the covert signals. She assisted the government in tracking and apprehending the miscreants.

In my wild and misspent youth when I was using 11 meters, I used a VERY large amp which would cause some neighbors to hear my voice coming from electric sockets, refrigerators, light bulbs, radios, TVs and such. I

would also voice over anyone close who was recording on tape.

My electric bill was rather large as I had to unplug the stove to use the 220 socket.

On the other hand, there were spark transmitters well before that in a similar power class. As I understand it, the powers actually achieved as output were often either not well known or were kept quiet for various reasons, but they were clearly in excess of 100kW. Apparently the Oct. 1920 issue of "General Electric Review has an article by Alexanderson about a 200kW alternator-driven transmitter. I understand that there were also some high-powered (Poulsen) arc transmitters (quite distinct from the shock-excitation of spark). I found one reference to a Poulsen arc transmitter that ran at 3.6 MW input power which was "still active in the early 1920s..." It ran on ~50kHz. Pretty much all this early stuff was below 100kHz, which of course yields very reliable propagation if you put enough power into it.

Our plant used to be less than a wavelength from a 1MW transmitting system, and I was always somewhat surprised that we weren't bothered more by them, as we made sensitive spectral analyzers that covered the frequency range on which they transmitted. We moved, and now we're a couple wavelengths away. We're more bothered by the 5kW AM broadcast station a few miles away, though that's easily filtered/shielded.

Cheers,
Tom

935. Fluorescent light RFI solved

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-06 06:01:32 UTC
From: News Features <news_features@newsfeatures.net>
Message-ID: <17bmk.18297$89.414@nlpi069.nbdc.sbc.com>
Source record: 23609

I'm not sure if this is the right newsgroup for this, but I wanted to get this information out there to help others.

Our electrician arrived with brand new fluorescent under-counter lights to install in our new kitchen. I told him, "Hey, I already bought lights at Expo! Can you simply install mine?"

For some reason he was very reluctant to install my lights. He insisted that his were just as good, if not better, than mine. I didn't have a strong preference so I let him install his lights.

When it was finally dark, my wife turned them on to get the full effect. To my horror, the AM radio two rooms away was instantly and completely obliterated with RFI. I ran out to the shack and confirmed noise all the way up to 20 meters.

The next day, I removed his lights and installed mine, and I was extremely pleased to note not a hint of noise on any frequency, unless the receiver was < 6 inches from the light.

His lights: Bright Inch by Elite Lighting.

Mine: SlimLite by Hera Lighting.
http://www.heralighting.com/hera/slimlite.html

They cost more, but they're worth every penny.

Regards,

Al W6LX

Hello, and I grew up in Cincinnati where Crosley might well be regarded as
Cincinnati's equivalent to Pittsburgh's G. Westinghouse. Don't know if
Cincy had a Tesla, though ;-) The operations of WLW over the years are
well documented in technical journals and newspapers so I would ask of the
OP what is his information source(s). Sibncerely,

Absolutely. No question that the great flood was a localized phenom. I was just getting in my occasionall dig at those who would demand that since it says so in one book, it had to have been the world.

The bible is mostly enjoyable reading as long as we don't get tripped up on the whole literal thing.

940. Re: The Strange True Story of a Radio Station's Transmitter in New York State

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-06 15:10:02 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <Q9jmk.12260$KZ.4425@newsfe03.iad>
Source record: 23614

Quoting from the original post in this thread:

"People in New York didn't even need radios. They could sometimes hear voices in their furnaces
and coming off chain-link fences. Light bulbs lit up in people's houses even if they were switched off. "

These are the phenomena reported from WLW's 500 kw operation in the 1930's.

Some posters on this thread mention spark, Poulsen, Alexander alternators as sources of 500 kw and Mw power in the 1920's, which is true. On the contrary, from the quote above, I believe the original poster was referring only to a station broadcasting voice transmissions. This is what I believe to be untrue, as I don't believe 100 kw tubes were available in the 1920's. In addition, the WLW story indicates that WLW was the first station to transmit with 50 kw, and then the 500 kw transmitter with multiple 100 kw tubes was the first one to transmit AM BC at that power.

The other day I was operating on 40 m SSB with 1KW+ output. Antenna is an
inverted V at 50 feet. My mother told me she could hear my voice coming out
of somewhere on the second floor. There was nothing with a speaker in it
that was turned on, not even a PC. I will have to repeat that with a ham
friend present.

But WLW ran 500KW of 100% AM modulation. I understand just the modulation
transformer was the size of a room in order to handle the 250 KW of audio. I
believe it was on 700 KHz. See the link I gave above.

Thanks for posting this, Al. As we get into more and more expensive electricity, there's ever more pressure for all of us to reduce electrical consumption by using fluorescent lighting, much of which results in completely unacceptable rfi noise levels. Does anyone know of a database that rates various brands as to rfi?

Bob

Well, admittedly I was taking it a bit out of context, but my posting was a response to Walter's "Do really believe that there was a transmitter in the 1920's that could deliver
500 kw?" And the answer is, yes, I do. Maybe not valve-based, but more than one transmitter, and capable of modulation as well: apparently Poulsen arc transmitters were FSK, since they couldn't be keyed on and off. And apparently the alternator based transmitters could be keyed at up to 100wpm. I'm pretty impressed with what the radio engineers of that era were able to achieve.

Cheers,
Tom

The UK back in the 1950s, post WWII.
They were investigating some complaints that a licensed amateur radio
transmitter was causing interference to some of the new fangled TV
sets (45 megahertz, AM sound, 405 line black and white system). The
fault was mainly the inabilities of the TV sets to reject strong
nearby signals in another band!
One elderly lady was asked if she was "Hearing anything" and replied.
"Oh yes. I hear him all the time" and was asked to show the
investigators her TV set.
"Oh no", she said, "I don't have a TV at all but I can hear him on my
electric heater whenever I switch it on or plug it in!".
Turned out that the heating coil of the heater was providing
inductance, there was a sufficiently high resistance (possibly where
the replaceable heating coil connected at each end) to act as
rectifier under the conditions present and the metal frame of the
heater provided a sound box.
The lady was not particularly concerned about having the heater fixed,
saying "She found his talking quite interesting!".
You never know do you?

Nowadays sort of wondering about cell phones and those bits of metal
that some people wear in their noses, faces and ears etc.

> Can anyone clear this up for me?

One thing that has not been mentioned IS that if your dealing with
GeoSync SATs, they are spaced VERY Close together, and sometimes
actually just a few miles apart, across the Clark Belt. This means
if you have a Transmitting Antenna that can't be directed at just
one SAT Position, (better than 2 Degrees) you will be illuminating
more than one SAT, AND consequently, if those multiple SATs have Inputs
in the same Band as your up-linking, you will be using other folk's
spectrum and transponder space, which is a GIANT NO NO. You are
REQUIRED to use an Uplink Antenna that will only illuminate just the SAT
your licensed to work, and that includes any Side-Lobes off your antenna
as well. This is why Parabolic Antennas are almost ALWAYS used in
Uplinking to GeoSync SATs. They tend to have very tight Beamwidths,
and few sidelobes that get in the way. Panel and Slot Arrays just don't
have the Beamwidth Control and Minimal Sidelobe specs for this type
of use, and that's why they aren't used in this application.

There is your problem, right there.... RG-58 is not really very good at
VHF Frequencies in lengths longer than 25 Ft. You should get some good
cable, like Beldon 9913 or LMR400 and have someone who knows how to
install the proper connectors on it, do the work, of replacing the
Feedline. I suspect your losing over 50% of your signal in the Feedline
and connectors.

948. Blackberry power level 4.9GHz

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-06 19:37:22 UTC
From: HarryHydro <harryhydro@hotmail.com>
Message-ID: <82d0284e-bece-4572-9860-0ee36a42b80d@z72g2000hsb.googlegroups.com>
Source record: 23622

Hi Folks:
We've been having intermittent problems with 'interference' on
6.8 gig Alcatel radios and 5.8 gig (freeband) Proxim radios. I just
came into the radio shack, turned on the 'widow maker', a big heavy
spectrum analyzer, and instead of finding 5.8GHz internerence, I
found VERY strong pulses of RF around 4.9GHz. With my Blackberry about
5 feet away, the analyzer is showing a -10dbW (yes, 100mW) on a 2.4
gig antenna. It must be saturating the front ends. This Blackberry
comes through speakers with the preamps, and even televisions a good
10 feet away! It makes the computer monitor's screen shake almost
like the degauss! (when placed close). And, I suspect it does this
with it next to my head also, straight out the front and back of the
phone.
I was just looking at 4.9gig info and it seems to be allocated to
public safety. Is it also WiFi? The WiFi on this phone is off, at
least in the 'Connections', but that doesn't suprise me as laptops
seem to transmit on WiFi while connected to LAN. (Laptops' WiFi
knocks off the Proxim's, also)
Anyone ever scoped out the RF power from a Blackberry? Can this be
safe power levels?
Harry

How long is the RG58 cable? Did water get into it? If so, consider replacing it with RG8X (same impedance, lower loss).

Not really antenna related, but...

They are ostensibly Part 15 compliant, so one could look at the
certification paperwork they supplied to the FCC.

I wouldn't count on huge amounts of item to item consistency, even
within the same brand and model. Based on my admittedly anecdotal data,
there's a fair amount of manufacturing variability, so unless someone is
going to go out and collect data on a statistically significant sample
(which practically means tens or hundreds of units tested), any set of
measurements is valid only for the item measured.

I think the operative word here is "deliver", by which I would mean
"radiated into the far field". Dissipating half a megawatt in the
system is impressive, but not necessarily as a transmitter.

And the answer is, yes, I do. Maybe not valve-based, but
> more than one transmitter, and capable of modulation as well:
> apparently Poulsen arc transmitters were FSK, since they couldn't be
> keyed on and off.

One scheme was to change the resonant frequency of the antenna (via taps
on a coil), which was the frequency determining part of the system, the
arc providing a negative resistance characteristic for making an oscillator.

And apparently the alternator based transmitters
> could be keyed at up to 100wpm. I'm pretty impressed with what the
> radio engineers of that era were able to achieve.

It IS very impressive, but whether they could *radiate* half a megawatt
is sort of a good question.

Consider for comparison the ELF transmitters in Michigan..several
Megawatts to radiate less than 10 Watts

Or Project Sanguine, which was soemthing like 800 MW to radiate a few watts.

I know of several Tesla coils that have average power inputs in the
hundreds of kW range, but they don't radiate a whole lot, even with 20+
meter sparks as an antenna.

>

1/2 degree kinds of beamwidth aren't that tough to get. (a meter or two
aperture at 10GHz gets you in the ballpark, a third that at 30GHz Ka-band).

beamwidth is almost entirely a function of the physical extent of the
antenna (that is, a 20 meter antenna will have comparable beamwidth,

regardless of whether it's a reflector or phased array)

Sidelobes are a function of the control over amplitude and phase across the aperture. You can use a smooth surface (as in a reflector) or good element and feed design (as in a low sidelobe phased array). There are phased arrays (electrically steerable no less) with sidelobe levels more than 50 dB down. That's an impressive number for ANY antenna (for a reflector, you're going to be paying a lot of attention to surface finish and even more to the feed design)

You might want more aperture on an uplink for the gain, as opposed to the beam properties. You could spend more on the fixed antenna and less on the power amplifier (e.g. use a 12m antenna instead of a 6m antenna and a PA that's 1/4 the size.. either one will have a beam that is substantially bigger than the satellite you're pointing at). There *IS* a limit.. cost starts to rise pretty quickly above a particular size, because the structure to hold mechanical tolerances is big and expensive. (e.g. the Deep Space Network 72 meter antennas cost a good chunk of a billion dollars back in the 60s)

It's more a cost thing. If you only need to point in one direction at one frequency, and it needs to have large physical aperture, then a fixed reflector is probably the cheapest solution (particularly over life).

Here's a relatively old design (1969) at 16 GHz with 3 degree beamwidth, pretty decent sidelobes, and steerable over 60 degrees

I've had old solid state console stereos at the place I worked spew forth
the local CB'er w/linear even when not plugged in. We figured that the
output transistors were detecting the signal and feeding it to the speakers.

From Joe Rice's (W4RHZ SK) book "Early Cincinnati Radio, 1910-1970":

The history of WLW presents a story of American enterprise and ingenuity
as colorful as any story in the world. It has the distinction of being
one of the few radio stations in all of American of running 500,000
watts of power. This is did from New Years Eve of 1934 until 1939.
From a modest beginning of about 20 watts power to the super power
range is a real success story of one man. Growth of WLW was constant
and it operated on different wavelengths until 1927 when it stabilised
at 700 kilocycles and then in 1928 it increased power to 50,000 watts."

Right, Walt. Rice's book indicates that there were 31 tubes in the 500
KW transmitter, each costing $1,000 in 1934. The Cincinnati area
stories of people living near WLW's Mason, Ohio transmitter site being
able to hear the station on fences and down spouts were common.

Even at 50 KW, WLW caused problems for a number of hams who lived near
the transmitter site when they were operating on 160m.

The modulation transformer at VOA's Bethany relay station (located quite near WLW's Mason, Ohio transmitter site) took up much of a very large room. If you stood in that room, you could hear the transmitted audio from the laminations. The sound was so loud that it was necessary to shout to be heard over it.

Well, my report is certainly anecdotal. No measurements beyond turning on the AM radio and bringing it up close to the lights were made. However, I can believe that perhaps the electrician got a bad batch of lights. Maybe the ground was missing or some filter or something like that. However, it is highly unlikely that the (good) Hera lights happened to be totally quiet due to some manufacturing variability. In other words, manufacturing variabilities can and frequently do result in really bad units, but rarely result in phenomenally better units than the norm. What this tells me is that the Heras have a better controlled manufacturing process. If that's all you got from my post, then I submit that that is a valuable data point.

(The web site of the "bad" lights says that they are California Title 24 compliant. I have no idea what that means.)

Let's put it this way: given my merely anecdotal experience, if you had to buy undercabinet lighting tomorrow, which would you buy? That's all you can get from anecdotal evidence.

Interesting, but from past experience, the results may be just the opposite a few months later because the source of the components may change over time.
The components of fluorescent fixtures consists of
The ballast - which is usually outsourced by the fixture manufacturer. Ballast types vary - GE, Universal, Advance, and several other Ballast makers sell to fixture manufacturers.
The sockets - usually made by Leviton or Eagle or Rodale - but there are others.
The lamp (the fluorescent lamp). Usually are not provided by the fixture manufacturer. Made by Phillips, GE, Sylvania, etc.
Some even have a 'starter'.
--I expect the ballast is the critical component - some are magnetic, some are electronic - its probably the culprit

In the late 1950's White's Radio Log reported XEX (Mexico City) had a megawatt of power for a while -- several years, perhaps. Later reports gave their power as 500 KW. I never heard them in NY because there was always somebody else blocking them. Presently they're on 730 and listed at a featherweight 100 KW.
http://www.fcc.gov/fcc-bin/amq?list=0&facid=101201.

What's the record for max BCB power?

Bill,

Yep, Joe was a Norwood boy who became a Northern Kentucky transplant.
I was WB4KTR when I moved from Miami to Fort Thomas in 1968. I didn't
meet Joe until coming back from the Air Force in 1972. He was my first
160m contact, good for about ten miles. :-)

I found the Early Cincinnati Radio at a used book store in downtown
Cincy in '73 or so. I have two other books by Joe which he inscribed to
me. One is called "Cincinnati's Powel Crosley". The other is entitled
"Early Norwood Radio"

Joe was a bit eccentric but he certainly knew his stuff about broadcast
radio. He was engineer at many of those Cincinnati area stations and
worked, at one time or another, for many of the electronic/radio
manufacturers in the area as well.

I, too, was an NKARC member until I moved across the river in 1977.

73,

Dave K8MN

Hello, Hal.

I suspected the electronic ballast in the "bad" light myself. They both use electronic ballasts. Perhaps it's an unfiltered ballast in the "bad" light or something like that. They both are supposedly made in the USofA so I can't blame it on the Chinese tendency to eliminate unnecessary items like filter capacitors to save 18 cents of the cost.

I hope you're wrong about the two lights switching places; somehow, I can't imagine the "bad" light gradually becoming RFI-quiet over time... by what mechanism could that happen?

I am judging the lights as they are... one is noisy, the other is quiet. It is somewhat amazing that we are trying to make excuses for this situation rather than accept that some lights are noisy and some are quiet! :^)

Dunno, but some of the SW BC stations sure are impressive. I had the opportunity to see the Deutsche Welle facility at Wertachtal, Germany a couple of years ago. It has, I believe, 12 ea. 500 kW transmitters, and the antenna consists of several miles of curtain array with reflector grids on both sides for reversibility, arranged in a pattern of three long radials from a central building. It can also be electronically steered to some degree. Modulation could be heard at about a half mile from the antenna, apparently from vibration of some of the antenna feed components. That facility leases time to many other international broadcasters.

I can think of one, but it's obscure and unlikely. Some electrolytic
capacitors must be "formed" by application of voltage to develop their
rated characteristics. (However, it's applied DC that usually does such
forming, and I think all production flourescent lamps run exclusively on
AC.) If an unformed cap were installed as a filter and if it were later
formed by applied voltage, that is the mechanism that occurs to me.

Contradictions welcome.

No power level is "safe". Safe enough is another matter and is subject to
one's beliefs. There is very little science behind the establishment of safe
levels.

It turns out that I have too many transmitters in a small area so the frequencies are getting on top of each other. I can use half at any one time. At the moment I have 6 running and am adding them one by one to see how far I get before I start losing them. Hopefully I won't have to change the frequencies on too many. Fingers crossed :)

In 1953, XERF at 250 KW in Villa Acuna was the strongest
station on the dial in East Texas. Their studios were across
the Rio Grande River in Del Rio, TX. For some reason, I
remember the White Rose Petroleum Jelly commercials.

True enough, but for the naysayers, I always issue the challenge of
taping a wire from a 5 watt RF source to their temple.

No wonder, then, that they can put a 0dBm signal into a decent ham
antenna on 7MHz on the US East Coast. Still, I'm always in awe of the
efficiency of propagation through the air, bouncing between the
ionosphere and the earth/oceans. On the same roughly 5000 km path
through a piece of dry air insulated minimum loss copper coax 1/3
meter diameter (a bit over a foot diameter; about 5 millidB/100feet
loss@7MHz), fed 6 megawatts at the input, you get an undetectable
signal out the other end, over 800dB loss yielding an output less than
-700dBm. [6 megawatts at 76 ohms is 21kV rms, so a line that large
should handle the voltage, but at the transmitter end, such a line
would dissipate about 60 watts per foot.]

Cheers,
Tom

I don't think any of the "national" radio stations
in the Mideast run more than 1 Megawatt. Here's
some interesting stations from the Americas:

PJB3 800 kHz ND1 Daytime TRANSWORLD R 800.0 kW
ZYJ-457 800 kHz ND1 Daytime RIO DE JANEI 900.0 kW
YVTB 800 kHz ND1 Daytime MARACAIBO 5 900.0 kW
YVKY 710 kHz DA1 Daytime CARACAS 11 900.0 kW
YVKG 950 kHz DA1 Daytime CARACAS 2 400.0 kW
YVLL 670 kHz DA1 Daytime CARACAS 9 500.0 kW
ZYH-446 740 kHz ND1 Daytime SALVADOR BR 800.0 kW
ZYH-707 AM 980 kHz ND1 Nighttime BRASILIA 600.0 kW
ZYK537 AM 1040 kHz ND1 Nighttime SAO PAULO 900.0 kW
ZYJ-455 AM 1280 kHz DA1 Nighttime RIO DE JANEI 700.0 kW
HCXY1 AM 620 kHz ND1 Daytime LOJA EC 900.0 kW
HCJB1 AM 690 kHz ND1 Daytime QUITO EC 600.0 kW

I'm curious, what does the ballast do? I see it referred to on light
fixtures I've installed, but I've never quite figured out what it is.

GE makes an RFI Filter that can be added to standard 4 Ft Tube Ballasts,
and that will eliminate MOST MF/HF Fixture Interference. I have been
using them in Alaska for years.

All these bulb work by passing current through an ionized gas. The
forward voltage drop across the tube goes down as current goes up (a
so-called negative resistance characteristic). If there weren't
something to limit the current, it would rise to the point of
destruction. You could use a resistor, but it's lossy. All you need is
some impedance, so an (almost lossless) inductor works fine. That is,
hook up an inductor with a reactance of 100 ohms to a 100Vac source, and
you'll get a current of 1 Amp, but no power is consumed because the
current is out of phase with the voltage.

You could also use a constant current regulator to do the same thing.
If the regulator is a variable duty cycle switcher, then the loss can be
quite low. That's what's in the electronic ballast... essentially a
constant current source.

In practice, there's some more aspects to getting a fluorescent lamp
started.. you have to ionize the gas inside, which you can do either
with a filament (gets things rolling, and once current is flowing, the
current in the gas keeps it ionized) or with a high voltage pulse (like
a flash tube).. (this is the difference between the "thermal starter"
where you see the tube glow reddish at the ends at the beginning, and
the "rapid start" types)

(This is also why fluorescent lamps are dimmer/harder to start in cold temperatures..)

Where the term "ballast" came from, I don't know.

No No - when I mentioned changing places - I'm talking about the brands at an arbitrary time in the future, should the same experiment be run at another time in the future - using new fixtures at the time *(not the ones you have now)* I would not expect the noisy one to fix itself, and I wouldn't expect the quiet one to become noisy out of the blue.
sorry if I was unclear.

The ballast serves two purposes -
it 'strikes the arc' (starts the current flow)
and it
Limits the current flow
(otherwise current would spike and destroy the fluorescent lamp)

The efficiency of a fluorescent fixture is dependent partly on the ballast -
and usually - electronic ballasts are the more efficient of the two. HPF
ballasts usually use less current than a standard ballast.
You Compare fixture efficiency by comparing the ballast specifications
assuming they use the same lamp.
The web site that John Smith posted a link to explains it pretty well.

Possibly from the meaning "imparting stability." A ship's or boat's ballast does that. Ballast around railroad ties does that. Ballast in a hot air balloon does that.

A ballast tube in the filament circuit of a certain radio of my acquaintance, the R-390A/URR, stabilizes the filament current for two oscillator tubes, the VFO and the BFO.

Why not go out in the sun without a hat?
Show me who has been harmed with a 5w Rf source taped to their head? (unless
they were sniffing exhaust or some other uncounted variable at the same

time)

Now stand in front of an XM terrestrial station - A bit too much I'd say,
but still can't prove it. Never gave the Blackberry sites a second thought.

If they are sending data at the same intervals some will walk on each other
every time.

986. Phase array question

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-08 00:55:29 UTC
From: Joel Koltner <zapwireDASHgroups@yahoo.com>
Message-ID: <7QMmk.58$5p1.45@en-nntp-06.dc1.easynews.com>
Source record: 23560

I've taken college classes in antennas and hence have a pretty good feel for some of the mathematics behind it all, but I've found that at times I don't have good, intuitive explanations for various antenna behaviors -- and I'm not at all good at being able to look at some fancy antenna and start rattling off estimates of the directivity, front to back ratio, etc. -- so I wanted to ask a simple question on a two-element phased array:

First, start with one antenna. Feed it 1W, and assume that in some "preferred" direction at some particular location the (electric) field strength is 1mV/m.

Now, take two antennas, and space them and/or phase their feeds such that in the same preferred direction the individual antenna patterns add. I.e., we're expecting a 6dB gain over the single antenna (but only at that location). Since we start off by splitting the power to each antenna (1/2W to each), that initially seems impossible, since 1/2W+1/2W = 1W --> should imply the same 1mV/m field strength. But this is an incorrect analysis, in that powers don't add directly. Instead, the fields add... hence, each antenna alone will now produce 707uV/m (at the one particular location in question), so the two together produce 1.414mV/m which is the same as if the single antenna had been fed with 2W. Hence the 6dB gain we're after! (This analysis also implies there must be other locations that now receive <1mV/m in order to conserve energy.)

Is that correct? "Powers don't add, field strengths do" is obvious enough, but definitely leads to some slightly non-intuitvely-obvious (to me) results. By extension of the above, though, it becomes obvious that (in theory) one can build an array with any desired amount of gain, the beamwidth just has to become narrower and narrower, of course.

Thanks,
---Joel

There are two errors in your analysis. The first is that you've neglected mutual coupling between the elements. In some special cases, this will result in equal feedpoint impedances, so that equal powers will result in equal currents, which in turn result in equal field strengths. But that happens only in special cases and not by any means all cases. In the general case, splitting the power equally between elements won't result in equal fields from them.

Moving on, let's assume that you've got a special case where the equal power split results in equal field strength. Your analysis is then correct up until you calculate the dB gain. Your correct value of 1.414 mV/m is correct, but it represents a 3, not 6, dB gain relative to a single element (which produced 1 mV/m). In the absence of mutual coupling, and if the elements are spaced and phased such that there's

some direction in which the fields can completely reinforce, then the maximum pattern gain relative to a single element is 10 * log(N) where N is the number of elements, e.g., 3 dB for two elements, 6 dB for four elements, etc.

For a much more detailed explanation of these phenomena, I recommend reading the treatment of phased arrays in Chapter 8 of the _ARRL Antenna Book_. I'm admittedly a bit partial to this particular treatment, since I wrote it.

yes, all true. and that is where many of the arguments on here begin,
trying to add powers instead of fields, voltages, or currents. and yes,
theoretically you can keep making the beamwidth narrower and get more and
more gain, that is one reason lasers are so intense with such low power,
they have extremely narrow beamwidths.

It's also 'true' that to get more gain in one direction you
typically have less gain in some other direction. You can't get
something for nothing, so you are only redirecting what you've already
got, so to speak (how directional antennas work).

Joel Koltner wrote:
> "Powers don't add, field strengths do"

"Add" is a rather loosely defined term. A more technically precise statement would be: "Powers don't superpose, field strengths do." When fields superpose, they still must obey the conservation of energy principle, i.e. the total energy before the superposition must equal the total energy after the superposition.

Given two RF waves in a transmission line and the phase angle, A, between the two electric fields, the following Power equation, published in QEX, gives us a valid method of "adding" two powers.

Ptotal = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

Reference: "Wave Mechanics of Transmission Lines, Part 3", by Steven R. Best, VE9SRB, "QEX", Nov/Dec 2001, (Eq 13), page 4.

The last term is known in optics as the "interference" term, positive for constructive interference and negative for destructive interference. Angle A, the phase angle between the two electric fields, determines the sign of the last term and thus whether interference is destructive or constructive.

Reference: "Optics", by Hecht, 4th Edition:
Chapter 7: The Superposition of Waves
Chapter 9: Interference

What Roy did not tell you is that his program has a free demo version
(http://eznec.com/) that will will provide quick answers. The learning
curve for EZNEC is pretty sharp for about 10 minutes and then it
shallows out.

Nope, that isn't the question. I neither confirm nor deny that long term exposure to FR at frequencies near those used in microwave ovens is harmful. Heck near field exposure may even be beneficial. I'm not saying one way or the other.

The great irony is that people buy their children cell phones, and the kids spend every free minute with them pressed to their head, but if we were to run an experiment that exposed the kids to RF in an exact analog of what they are doing anyhow, they would go nuts - as well they should! Would you?

I'm looking for those who think it isn't dangerous to have the courage of their convictions.

Haven't found any yet. They actually might be on to something, they just don't know it.

Yes, I assumed it was negligible. When we analyzed arrays in class some years ago, the starting point was always, "assume each antenna has the pattern of a single dipole in isolation, is matched to the transmission lines, with input current 1A @ angle <whatever>." We did analyze the patterns for a couple of local Oregon TV & radio stations, BTW, including whichever radio? station it is up in Portland (very roughly) near you off of I-205 as you drive past Oregon City.

> But that happens only in special cases and not by any means all cases.

The phased arrays I had in mind were those that were usually separated by a "significant" fraction of a wavelength, e.g., lambda/8 or more. That's probably not far enough apart to neglect coupling?

> Your correct value of 1.414 mV/m is correct, but it represents a 3, not 6,
> dB gain relative to a single element (which produced 1 mV/m).

6dB vs. 3dB is a rather embarassing outright brain fart on my part. :-) (The usual case of confusing "twice the power = 3dB" with "twice the voltage = 6dB").

> For a much more detailed explanation of these phenomena, I recommend reading

So... let's see... my two 1/2W antennas now, in the "preferred" location, get you... 0.5+0.5+2*sqrt(0.5*0.5)*cos(0) = 2W... yep, same as the field strength analysis. Cool!

Presumably you could demonstrate all this with a "ripple tank" (the kind with water used back in high school physics) -- set things up so that, in a preferred direction, the wave height is 1.414 even though the wave height made by each "radiator" in isolation is 0.707.

Thanks Cecil,
---Joel

Hi Mike,

Unfortunately, by your conjecture
>> I always issue the challenge of
>>taping a wire from a 5 watt RF source to their temple.
this implies a co-equivalent risk where neither activity have any data
to support that a risk exists. Merely having a fear does not create
that missing data or Saddam's WMD would have been on display in the
white house rose garden.

>Haven't found any yet. They actually might be on to something, they just
>don't know it.

They actually might be grossly ignorant is more appropriate. The
positive spin is that with great fortune in luck, desire, or hope that
they (there is nothing "actual" involved) might (the illusions of a
gambler betting against the house) be on to something (a fog of
correlation masquerading as causation).

Those with the courage of conviction have more self-assurance than to
drop their lives to join any contest in a flood of whim. What your
challenge would reveal is quite the opposite: those who lack
faculties, are insecure, and hopelessly embrace the latest
superstition. Some swing their banners here without needing an
inviting challenge.

Let's simply return to:
>>>With my Blackberry about
>>>5 feet away, the analyzer is showing a -10dbW (yes, 100mW) on a 2.4
>>>gig antenna.
and examine this from first principles.

5 feet away from an uncalibrated antenna (the emission is at twice the
"2.4 gig antenna" whatever that means) is also 15 wavelengths away
(probably more, but 15 is certainly instructive). Is this a gain
antenna? That would remove some of the hot-house steam from this
orchid's appeal. The breathless "yes, 100mW" is the dazzle of looking
at the sun through binoculars.

However, let's put the issue of gain aside and accept this valuation,
along with the only known facts - that same 15 wavelength separation.

A simple model performed using a free version of EZNEC, employing a clear path, no disturbing environment (like a skull), and perfect, lossless matching of source and load gives a path loss of 45dB. That report of "yes, 100mW" requires the Blackberry to source something closer to 5KW.

It is more likely that -10dbW was "actually" -10dBm; and I am tempting credulity to even allow that.

Not by a long shot! Here's a simple example from the EZNEC demo program, using example file Cardioid.EZ. It's a two element array of quarter wavelength vertical elements spaced a quarter wavelength apart and fed with equal currents in quadrature to produce a cardioid pattern. The impedance of a single isolated element is 36.7 + j1.2 ohms. In the array, the impedances are 21.0 - j18.7 and 51.6 + j20.9 ohms, and the elements require 29 and 71 percent of the applied power respectively in order to produce equal fields. The deviation is due to mutual coupling. This particular array is a special case of another kind -- there is no net effect of the mutual coupling on the array gain, so it has 3.0 dB gain over a single element. This isn't true in the general case, however.

Neglecting the mutual coupling is convenient for the professors because it simplifies the problem and allows them to illustrate the simple addition of fields. The problem is that it leads some students to think they have the whole story.

In very large arrays such as those used for radar, the vast majority of elements are in essentially the same environment relative to each other so the mutual coupling has the same effect on all except the outer few elements. But it simply can't be ignored in arrays of a few elements.

Another source which has a good discussion of the topic is Johnson's _Antenna Engineering Handbook_, or earlier editions edited by Jasik. Be wary of amateur and hobbyist publications (other than the _ARRL Antenna Book_ -- very few authors understand the topic, and pass along their misconceptions.

That's a much, much greater difference than I would have guessed. Wow...

Isn't the input impedance of one element affected not only by the relative position of the other element, but also how it's driven? I.e., element #1 "sees" element #2 and couples to it, but how much coupling occurs depends on whether the input of element #2 is coming from a 50 ohm generator vs. a 1 ohm power amplifier (close to a voltage source), etc.? (Essentially viewing the antennas as loosely coupled transformers, where the transformer terminations get reflected back to the "primary.")

Thanks for the book links. Do you happen to have a copy of "Small Antenna Design" by Douglas Miron? And have an opinion about it? Or some other book on electrically small antennas? (Not phased arrays, though :-) -- more like octave bandwidth VHF or UHF antennas that are typically 1/10-1/40 lambda in physical size.)

Not directly. What counts (considering the simple case of two elements)
is the magnitude and phase of the current in the other element, and
their spacing, orientation, and lengths. A good way to look at the
effect of mutual coupling is as "mutual impedance", i.e., the amount of
impedance change caused by mutual coupling. (Johnson/Jasik covers this
concept well.) If you were to feed two elements with constant current
sources (as in the Cardioid.EZ EZNEC example), mutual coupling doesn't
change the element currents, but only the feedpoint impedances. With any
other kind of feed system, the impedance change causes the currents to
change, which in turn affects the impedances. So the feed method
certainly does have an effect on the currents you get, which affects
both mutual coupling and pattern.

There's a lot more about this, and how to design feed systems which will
effect the desired currents, in the _ARRL Antenna Book_.

I just recently purchased Miron's book but haven't yet looked at it in any depth. It appears to be most interesting to anyone wanting a better understanding of method of moments numerical methods. If you can read German, you might be interested in _Kurze Antennen_ by Gerd Janzen. But your search for small, broadband antennas puts you bump-up against the principle "small - broadband - efficient, choose any two". They'll be inefficient, which will hurt you both receiving and transmitting at VHF and above. The book I'd go to for researching the possibilities would be Lo & Lee's _Antenna Handbook_. You might also get some ideas from Bailey, _TV and Other Receiving Antennas_, since TV antennas have to be pretty broadband.

Funny, didn't someone just mention how it was known tobacco was harmful to us--long before there was "proper proof."

This argument would hold much more water if microwave freqs from .9Ghz to 20+ Ghz were not so efficient at heating/affecting water and other polarized molecules. Now, didn't I read, somewhere, that the brain is mainly composed of "fat"--fat IS a polarized molecule, and the brain does contain water ...

I think most prudent men would be leery of holding a device emitting freqs capable of cooking food next to their brain ...

Ever heard of bluetooth?

Cryptic, but if reference is made to 30Mhz and below (however, John Kanzius DOES burn sea water with ~13.56Mhz--and, our blood DOES contain, roughly, the same concentration of salt as sea water) ... not much worry here; But then, for decades men have been exposed to TREMENDOUS fields of these freqs--indeed, hang a turkey on a 5kw antenna, you'll eat a cold dinner.

On power, my bluetooth is lucky to reach 30ft. I am amazed at how far my cell phone reaches out to contact a tower ... I do get dropouts (queued packets are dropped because they have timed out of their "place in line", loss-of-signal and garble-ing in the valleys in the foothills and behind hills/mountains.

An ear-set/mic would be the best, however, I always tear the cord loose ...

The phone is always on the console in the car ... when I am home/office, it forwards calls to the internet phone.

I never claimed I could limit my risks to an absolute zero ... only that prudent men would worry about this subject--perhaps even enough to take precautions, which they are capable of.

In summary, if I wish to heat a chicken leg, a burner on the stove is best (or microwave <grin>.) However, I DO believe I could accomplish the same thing with my cigarette lighter, it would just take longer.

I had a similar problem but it was with just one light out of several.
I returned it for a new one of the same brand. Could it have been that
only one of the new lights was causing the problem. I have also had a
couple of the compact flourescent light bulb replacements cause
problems. They become noisy but still function.

Well, I did "stretch" the facts on one point, blood has about 1/3 the salt content of sea water (not meaning the content of "sodium chloride" specifically!--or, any other element ...)--however, the point was not being made on heating blood until it "burned"--but just to do "noticeable damage" ... I am sure you will grant me that "writers' license." <grin>

Back at about the same time the BBC had (and still has) a powerful transmitter on 200khz (now198) a local farmer who lived close to the station built a large tuning coil in the loft and lit his house using fluorescent tubes.

He was successfully prosecuted for stealing electricity or something similar.

That's the trouble with you people. You insinuate by "asking a question" or making up a meaningless phrase like "noticeable damage" or "common sense laws" in such a way that it panics the ignorant or non thinking people into running over a cliff or voting, then you sit back and feign ignorance. Just beware you don't get caught in your own stampede. I submit that power tools should be rendered safe before exposing them to people with "artistic license" or who feel themselves "not responsible" for their actions because they are crazy.

We know that the human body can be harmed by just sitting in the sun too long. How much RF at what frequency has or has not caused damage to those who have been or are exposed, has been addressed only by FCC setting an arbitrary specification without supporting data other than that supplied by military microwave studies with respect to high powered radar. Nor do the studies support that there is noticable damage by observing the military safety standard or by the FCC standard that sets limits much lower, and even lower still for those who aren't knowlegable on the subject.. So then it is anything but an objective issue. I too have been exposed, but limited my exposure based on time averaging, so I have encountered field-densities thousands of times greater than a cell phone for a several minutes and hundreds of times, for as much as an hour with no discernible effect in the long or short term, but have encountered unknown intense fields with short term issues, such as headache in the evening after exposure, but gone in the

morning. I have certainly encountered the same thing more often from over exposure to "a day at the beach".

Case in point: As a nonsmoker, I have problems reworking PC boards because my employer has no plausible deniability that any respiratory ailment I might succumb to in later years wouldn't arguably be caused by a self-inflicted lifestyle condition rather than an employment hazard.

In the face of other more serious health risks such as sunstroke, falling off a tower or electrocution, RF exposure is a common sense issue for hams and those in the business, and a non-issue for those who will never enter restricted areas. In fact, there are far more daily hazardous things that we encounter, as to obliterate any test data. Your Petri dish and saltwater experiments have less credibility than the anecdotal.

It's like the illegal alien issue. Due to the lack of proper judgment and widespread hysteria, more housekeepers and migrant workers will suffer than gangbangers who find prison to be a climate-controlled mailing address with a few inconveniences, but "three hots and a cot". Deportation gives opportunity for those with plenty of drug money to do it again. All the hysteria does is help to polarize nationalism (and foreign nationalism).

With the population of foreign nationalist gringo haters in this country outnumbering those in Mexico, why do we need fences at all? Perhaps for a start, we might plant more businesses in Mexico rather than having everything shipped all the way from China.

Now all you need to prove, is that the RF Power Density of a 300
Milliwatt Cellphone, operating one one of 4 Bands in the 800-900
Mhz, and 1800 - 2000 Mhz, will cause ANY Measurable Heating in
Human Tissue, and therefore cause some sort of problem. So far,
NOBODY has shown that to be the case. Not even in the 2.4 Ghz
ISM Band where BlueTooth operates, with significantly LESS
Power Density. There are enough of these devices around that
should all this "Wild Speculation", actually have Observable Effects,
the researchers into this area wouldn't be needing to do Statistical
Analysis, to Magically try and prove some nebulous Causal Effect.

==========
It might be useful to know that the RF power radiated by any cellphone
is dependent on the distance between the device and the nearest base
station.
In a built-up area or along the highway with nearby base stations the
power can be very low ,whereas at remote locations it can be as high as
2 Watts (at least here in Europe).
Living away countryside ,when using my cellphone at home the battery
drains rather quickly compared when using the device in town.
When holding the cellphone near my HF transceiver I clearly hear the
digi-noise.
For this reason I avoid using the cellphone while at home or at other
locations away from a base station.
My home is approx 8 km (5miles) from the nearest base station.

Yes, I have heard that argument before, with tobacco ... Nicola Tesla
once said chewing gum was more damaging than alcohol ... This URL:

http://en.wikipedia.org/wiki/Thalidomide

This drug was once thought "safe" and marketed/sold in over 50
countries. It was thought so safe, it was given to pregnant women,
causing innumerable birth defects in children (children born without
hands/arms/feet/legs/etc.

Your argument against caution is simply ignorance such we have seen in
the past ... some of us learned. Even when the BEST AUTHORITIES say is
is "OK", use caution!

> exposure to "a day at the beach".

OK, so do an experiment yourself to test the amount of damage!

1) Cut an opening in the door of your microwave.

2) Insert your hand.

3) Turn on the microwave for 5 seconds.

4) Repeat 1 - 3 until "noticeable damage" occurs.

5) Come up with a time you think it is "OK" to microwave your hand;
quite possibly, you may wish to consider a time MUCH LOWER (as a "test
standard", note that zero seconds will ALWAYS be safer) than the time to
do "noticeable damage."

(Disclaimer, the above is only meant as a warning to demonstrate the
ignorance of the previous posters logic -- i.e., IT SHOULD NEVER BE
ATTEMPTED FOR ANY LENGTH OF TIME!) Or, don't do this yourself, EVER!

ABSOLUTELY! OTHER things cause cancer/illness, a search of the internet
will provide you with countless and proven substances/tasks/jobs/etc.
which you should provide. If you think there is a real danger with ANY
job you take--QUIT--IMMEDIATELY! But then, you can't protect some from
themselves, those will die for their occupation/job. :-(

Hey, some will make a trade off and face such serious consequences to
their health and safety in exchange for money -- I only hope their
compensation is justified, at least to them. Again, some people cannot
be saved from themselves ... and then, once they have made such a BAD
decision, they only wish to blame others.

If you are too stupid to protect yourself, am I required to do so? (I
mean I will, but then, I will not let you work at places injurious to
you! I mean, for God sakes man, you will raise insurance premiums
through the roof!)

Well, I guess, declines in the American living standards, importation of 3rd world conditions here, lack of medical care for millions, untold people without home ownership, etc., is nice! -- if you like that sort of thing ... personally, I would seek other/more-positive solutions.

> With the population of foreign nationalist gringo haters in this country

Well, we could just give them everything, then hate them for having it and work for slave wages getting it back and just keeping fed, I guess; again, some people have different ideas.

Personally brother, I would move away from such conditions -- but that is just me ...

Ionizing radiation?

Sorry, I missed the point where that ever came into question ...
however, yes, chuck a neon tube in a microwave, the gases WILL ionize,
but then the bulb will probably explode, LOL!

Let's say just those figures are correct ...

My Motorola Razar V3 phone is approx. 6mm thick (when opened), and where the antenna is buried in the phone. This means the antenna can be no more than 6mm from my head if the phone lies against my head. Now, we assume the phone is emitting 300mw. This would be equivalent to 1.2w of power emanating from that same antenna at a distance of 12mm from my head. And, the latter would be equivalent to 4.8w emanating from the same antenna at a distance of 24mm from my head. And, the last would be equivalent to 19.2w emanating from the same antenna at a distance of 48mm from my head ... your higher figure, of two watts, is simply frightening ...

The lunacy is exposed ... correct any error you see in the above ...

I should have clarified "the meaning" in the above ...

Or, to summarize, 300mw sounds both UNGODLY and IRRESPONSIBLE, IMHO ...
I would suspect it to be much nearer 50-100mw ... and I can logic this
by the size of the battery and the time it lasts between charges. (no,
I have NOT taken the time to get the battery specs and do the computations!)

However, doing the math, 50mw is too much. And, an equivalent of 1kw
emanating from the antenna comes at MUCH TOO CLOSE a distance ...

Sorry I had to take two posts to make that clear.

Regards,
JS

Well, the 3.7v, 900mah li-ion battery lasts ~2hrs of continuous "talk
time", I have verified this ...

It seems 300mw (actual output!) is NOT unimaginable ... :-(

I am surprised, the BR60 li-ion battery is 3.7v @ 900mah ... the ~2hr talk time suggests 300mw is well within reason ... I am surprised the battery packs that kind of punch. :-(

Well, I can't explain anything rationaly to you because you are jumping wildly to conclusions like a cartoon character. All I'm saying, is that you need to objectively assess risks. If you can't do that you ought to be institutionalized for the safety of yourself and others.

The statistics of wireless devices causing harm are so off the radar there are none! And this is the smoking gun - if there were, they would have come forward by now from the 2 way and uwave industry with complaints, but I haven't heard of anyone in the business who HAS been harmed in my 30 years of experience. And that is 15 years under the old standards of RF exposure - NONE.

I invite anyone from the industry who reasonably thinks they have been harmed to respond. Particularly from the retired folks. I'm not talking about RF burns, as they are minor and pain has a way of causing you to limit that exposure.

You can eliminate the potential of risk entirely by throwing away all RF devices.

But don't stop there because of all the risks that you failed to account for, such as rolling out of bed in the morning or burning yourself making breakfast or tripping on the front steps or getting in a wreck on the way to work.

THAT is a major risk statistically, whereas the statistics of RF harm are unknown because no is so stupid, to cut their arm off or cut a hole in the uwave oven door AS YOU SUGGESTED just to get a chance to GET harmful exposure, which sort of proves my point about the general public having to try real hard in order to to be exposed to harmfull levels of energy.

Getting back to the cell phones and Blackberry's - and I thought that's what we were talking about - DON'T WORRY ABOUT IT! They really don't amount to squat! Honest!

BTW I put a mouse in a Litton uwave oven in 1983 for 10 seconds and removed him because I didn't want to push the little guys luck or see him suffer. NO noticeable or discernable damage or harm was done and he went on to sire several healthy normal litters.

Sorry about that. I did get them mixed up not having the photos in front of me when writing. Roy is also correct. All that is in the ARRL Antenna Handbook. I believe impedance is lowered though at the dipole elements apex. to some extent. The dipole vs. Inverted V comes to mind, but the feedpoint impedance of a LPDA is really about the spacing of the feeders and matching system. .

I'll shut up now

Of course, our "difference" could stem solely from differing definitions
of the word prudent, such as in "prudent man."

I am using this definition:

Source: Webster's Revised Unabridged Dictionary (1913)

Prudent \Pru"dent\, a. [L. prudens, -entis, contr. from
providens: cf. F. prudent. See Provident.]
1. Sagacious in adapting means to ends; circumspect in
action, or in determining any line of conduct; practically
wise; judicious; careful; discreet; sensible; -- opposed
to rash; as, a prudent man; dictated or directed by
prudence or wise forethought; evincing prudence; as,
prudent behavior.

Moses established a grave and prudent law. --Milton.

That is a lot, and WAY overly complicated, IMHO ... and no, I don't need do all that ...

I need only "error on the side of caution." (If only I'd done that with smoking!) But then, that is keeping with the theme of "prudent man/men", which was my original statements intent.

Besides, Bluetooth improves the whole "phone experience", hands free digit dial and name dial are very handy. And, it is a law to be hands-free on the phone while driving an auto in California ... :-) A win-win situation which has few equals. Your particular mileage may vary ...

1037. 600 ohm balun vs 200 ohm balun

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-10 15:24:54 UTC
From: Edward Feustel <efeustel@hughes.net>
Message-ID: <rh1u945om5288a5dvnqaobsmd2q64k8v7t@4ax.com>
Source record: 23511

I have a centerfed 220 foot dipole I am using on all bands from 160 -
10 meters. It is between 40 and 50 feet above silt soil and is fed
with W7FG open wire (600 ohm?) Currently I am using a 4:1 balun at the
output of the antenna tuner to transform impedances to an L-Network
that allows the transmitter to see a close match at 50 ohms.

I am interested in opinions on whether it would be better for me
to use a 450 or 600 ohm balun that might more closely match the
transmission line (in practice).

I believe that with the reactances involved, so theoretically it might
not make much difference. Anyone with actual actual experience
who would like to render an opinion?
Thanks,
Ed

Check out Snopes on that. There are some Fake YouTubes on that too. It seems you can't even do that with a pile of phones. Nor can you receive police calls on your cell phone by spreading peanut butter on the SIM card. But if it is any consolation, I can grab on to a 50 watt 2m antenna and feel it get warm. Again, I can stand in the sun and get warm too. Aside from the known UV exposure problem, the tissue heating appears to have little negative impact over the long run when taken in moderation.

Still, people have been killed in their sleep by electric blankets. And I would question the sensibility of someone who stands in between two 10db 900 MHz 1kw ERP paging antennas just to get warm. But I've seen that done too.

Studies show that the penetration of RF heating into the body is tied quite a bit to the wavelength, and that the greatest penetration was somewhere between 400 and 2000 Mhz. The most worrisome issue was found to be the human eye at those frequencies. There is no blood flow in the Vitreous solution in the eyeball to cool it, nor in the Cornea tissue. Nor are you apt to notice if there is heating of that tissue. One of the long term results of the Military observations, were cataract formation in those who worked closely with microwave RADAR energy. You should be more concerned with the 5 watt 440 or 800 HT with the antenna right in your eye than your earlobe, which has blood flow.

If you notice your earlobe getting warm, reduce your talk time accordingly. And don't watch the food cook.

Just to clarify, you seem to imply, a 1.2288KW, equivalent, source of freqs in the "cooking bands" and at a distance of 384mm/38.4cm/~15-inches from your head is "nothing to sweat." (and given, the sources antenna is omni-directional)

Surely you can see how some men would withhold agreement ... at least until a time in the future ...

Hi Ed,

You can easily dismiss the theory and take the quick step up to the
bar of experience - your own (who better?).

Does it match on the bands you prefer? Changing things will not
improve what is already acceptable.

Are you worried about what you cannot see? Loss? Ah! Then we
migrate into the world of the skeptical and theoretical where there
are probably questions you cannot answer - which questions require
data to give you specific solutions.

You ask one of these questions (by inference) yourself: 400 Ohms or
600 Ohms? You don't know, but it "could" make a difference. Here,
the "could" is a question of degree. Yes, on paper it is significant,
but in practice the listener of your signal would never note any
improvement if you invested effort, equipment, and time in finding the
answer and implementing a change to correct the "problem."

Let's examine what is significant. Would you like to eliminate 1dB of
loss (make that 1dB available to the listener)? Do you know what 1dB
looks like on an S-Meter? I would suppose so: about the thickness of
the needle. Would you invest $1000 to do that? Which is significant:
1. 1dB;
2. $1000.

Feel free to adjust both numbers to more closely conform to your
situation and expectations and respond in that context.

450/50 = 9:1, 600/50 = 12:1 - Is that what you are thinking?

On a transmission line with standing waves, the impedance seen
by the balun will NEVER be the Z0 of the transmission line.

Let's say you are using Z0=600 ohm feedline with an SWR of 20:1.
Let's say a current maximum point exists at the balun. The balun
will see an impedance of 600/20 = 30 ohms.

Do you want to use a 4:1 balun and take it down to 7.5 ohms? Why?
Do you want to use a 9:1 balun and take it down to 3.3 ohms? Why?
Do you want to use a 12:1 balun and take it down to 2.5 ohms? Why?

Do you want to use a 1:1 balun and leave it at 30 ohms?

When the impedance being encountered by the balun is unknown,
a lot of experts recommend a 1:1 current-choke-balun.

1044. Re: Help me buy VHF/UHF television antenna? Can't decide!

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-10 16:35:42 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <V6WdnWi9a_pGhQLVnZ2dnUVZ_v7inZ2d@bright.net>
Source record: 23518

Dear JB (no call sign): The objective was in no way intended to stifle,
only to describe.

Here is the essence of my message about the 1080 of about a month ago:

It is deceptive to put numbers on the size. The reflector consists of five
doublets each with a tip-to-top length of 26.5 inches and a total height of
a little over 16 inches. The twin "driven" elements are spaced about 6.6
inches in front of the reflectors (obviously the reflectors are only
effective for UHF). The tip-to-tip length of the driven elements is about
34.5 inches (giving a predicted 0.5 WL resonance towards the bottom of the
higher VHF TV band). Each driven element is coaxial with a fan dipole that
should have a resonance somewhere in the UHF band. Thus one expects a small
gain with a small F/B in the higher VHF band and fair gain with good F/B in
the UHF band.

Ed, you could come to an opinion on this if you treat the system as
comprising lumped constant components.

But, it isn't simply that.

If you were to use a common mode choke, and that is probably the best
choice, eg W2DU style balun, the balun acts on the common mode Zo rather
than the differential mode Zo (the 450 / 600 you are discussing), so I
as why is the differential mode Zo so important in selecting the balun.

I know there are rules of thumb (ROT) about the parameters of the balun
wrt the differential Zo.

It is true that such a balun does contain a short length of transmission
line, and that means some amount of impedance transformation for loads
other than Zo, but IMHO it is not very significant in your tuned feeders
multi band dipole.

Obtaining an adequate choking impedance is probably a more important
issue, but people are usually more concerned about the correct Zo for the
balun.

Hate to leave that "hanging", like that ...

I found this:

"How can I obtain the Specific Absorption Rate (SAR) value for my wireless phone?

The FCC requires that wireless phones sold in the United States demonstrate compliance with human exposure limits adopted by the FCC in 1996. The relative amount of RF energy absorbed in the head of a wireless telephone-user is given by the Specific Absorption Rate (SAR), as explained above. The FCC requires wireless phones to comply with a safety limit of 1.6 watts per kilogram (1.6 W/kg) in terms of SAR.

Information on SAR for a specific phone model can be obtained for many recently manufactured phones using the FCC identification (ID) number for that model. The FCC ID number is usually printed somewhere on the case of the phone. Sometimes it may be necessary to remove the battery pack to find the number. Once you have the ID number, go to the following Web address: www.fcc.gov/oet/fccid. On this page, you will see instructions for entering the FCC ID number. Type the FCC ID number exactly as requested (the Grantee Code is the first three characters, the Equipment Product Code is the rest of the FCC ID number). Then click on "Start Search." The "Grant of Equipment Authorization" for your telephone should appear. Read through the grant for the section on "SAR Compliance," "Certification of Compliance with FCC Rules for RF Exposure" or similar language. This section should contain the value(s) for typical or maximum SAR for your phone.

Phones and other products authorized since June 2, 2000, should have the maximum SAR levels noted directly on the "Grant of Equipment Authorization." For phones and products authorized between about mid-1998 and June 2000, detailed information on SAR levels is typically found in the exhibits associated with the grant. Once a grant is accessed, the exhibits can be viewed by clicking on "View Exhibit." Grants authorized prior to 1998 are not part of the electronic database but, rather, have been documented in the form of paper records.

The FCC database does not list phones by model number. However, consumers may find SAR information from other sources as well. Some wireless phone manufacturers make SAR information available on their own Web sites. In addition, some non-government Web sites provide SARs for specific models of wireless phones. However, the FCC has not reviewed

these sites and makes no guarantees of their accuracy. Finally, phones certified by the Cellular Telecommunications and Internet Association (CTIA) are required to provide SAR information to consumers in the instructional materials that come with the phones. "

Truly, it didn't bother me at all. Of course, it could have been just a coincidence. I used to wonder if I had memorized their play sheet and then just applied that to the great sense of time that I had back then. I could come within a minute, twenty four hours a day, of giving the correct time each and every time someone asked.

The AM radio sense disappeared when I went into the USAF in 1965. When I came back from the USAF some four years later, the 1380 WAMS radio station was gone as was the use of the frequency. The USAF removed quite of a few teeth during my four year sojurn. I always figured that was the reason why radio reception stopped.

Well I certainly do, although I might be still an idiot.

I don't find a thing wrong with your logic. Fact is, no one would ever just allow the same RF source to be applied to their temples. They would say we're crazy to suggest such a thing. And much less to attach such a thing to their children.

Who here would tape a wire to their child's head with up to a watt of power running through it at those freq's ? Child protective services would probably declare you unfit, take the kids away from you, and you'd probably have to register as something or another so you could be tracked down if needed.

And yet, millions of parents do essentially the same thing, buying their children cell phones - and doing it "to keep them safe".

> I only hope to be here when they hand out the "Darwin Awards" to those
> deserving--post mortem-ously for them, most likely ...

Well, I still don't think they are likely to cause cancer. The frequency seems a bit low, and it's not as likely to cause cellular (hehe) problems as the ionizing type radiation.

I would suspect that the effects might be more likely to be involved with heating, or perhaps a disruption of normal brain activity.

Empirically, I have noticed that a lot of cell phone users behind the wheel bear a scary resemblance to extremely drunken drivers. Driving though red lights, sitting in a daze at green lights. Weaving off the road, erratic driving in general.

I think it is quite possible that excessive cell phone usage (hours/day) will make a person stupid.

I verified that each of the lights by itself was a problem. Bad manufacturing lot? Who knows? All I know is that they were unacceptably RFI-polluting. I got rid of them and replaced them with lights that were--right out of the box-- free of RFI. Problem solved. Hope this saves someone else the three hours of work it cost me.

There is no way I was going to go back to the store and buy four more of the bad lights on the basis of "Well, maybe four is too small of a sample size to draw any conclusions." Fool me once, shame on you; fool me twice, shame on me.

I reward companies that make RFI-friendly products and punish those that don't. Always have lived by that dictum. I also try at every turn to educate my neighbors to the same, so that we can all have as quiet an RF environment as possible. Hence, my purpose in posting the original post here.

Hi Mike,

Child protective services probably would do that even if you NEVER put
ANY rf through the wire. They would react to the obvious issue of
abusive behavior. They haven't got a clue what RF would do, and they
wouldn't distinguish between 1W or 1ï¿½W as being good, bad, or
indifferent; and it would be the height of absurdity to expect them to
rummage through their car trunk for exposure meters to figure that out
when they are faced with a wacko and nothing more needs to be sorted
out.

Again, this sort of logic (sic) merely perpetuates the nonsense Brett
Gump loves to forward through these threads.

I can imagine the drift of topic would speculate they would idly stand
by and wait for proof positive that the adult had finally warmed up
the Henry and threw the switch before they were legally obligated to
do what was long obvious.

>and you'd
>probably have to register as something or another so you could be

Using an ankle cuff with an RF link. Now, apparently, what is
dangerous to the head is entirely benign to the foot - tell this to a
diabetic. Care to assume the liability for this suggestion? Does the
hint of cuffs pinching your wrists come to mind?

This is the absurdity of Brett's Yellow Journalism research and how
the topic has drifted from the technical to the superstitious. Mike,
do you care to respond to my technical comment of 3 days ago, or is
this deviant speculation really that more relevant to anything?

First off, you need to use a proper setup and evaluation of the spectrum analyzer. A setup like you described can give wildly erroneous indications and even damage sensitive circuits. Just having multipath in the room can result in reinforcement of the signal. And you were standing where the signal was best? You aren't the only one caught by that. I never brought mine to work because "experts" had somehow convinced the powers that be that burnt out test equipment was a normal thing, so invariably only one or none might be working, being "in transit" to the depot.

A lot of devices are using modulation techniques that can be detected by analog devices, and nothing seems to more prone than amplified computer speakers. I can hear cell phone noise on mine even outside the building, even though they don't respond to my HF station with the linear on.

It doesn't make sense that energy 1 gig away would cause interference. I would be more suspicious of the audio circuits and switching transients. Consider that since RF power is on-off keyed, there is much less than 100% duty cycle of the On time, so heating effect are much lower than with FM.

Absolutely, to everything in your post! The data is much appreciated ... one thing I am still searching out is a transparent shield for the tubes themselves; I have considered a shield made of screen but have not acted on it (lazy/other-things-to-do.) I suspect rfi is using the plasma discharge in the tube itself as some type of inefficient antenna, as I have all shielded electronic ballasts ...

In addition, got any ideas here:

What do you do about wifi switches/routers/wireless-nics/etc?

It seems, to me, the frequencies which the Ghz signal(s) are modulated at, by the data stream of bits, is/are the real offender(s)? Other than the strategic placement of these devices and directional antennas, I have found little control over the RFI. I have found this to be a problem on AM/FM/SW/VHF/SHF; I have noticed, some devices/brand-names are less offensive than others ... I am, mostly all, Linksys with a couple of NetGear nics ...

Any ideas from anyone would be appreciated here ... and yes, any hard-cabling/power has been well choked with ferrite beads and filtered power-strips ...

I am asking because I have noticed, a person working to cure one form of RFI will, most likely, be working on "next one", next ... :-)

Hi, John,

I have found the exact same thing as you. The modulation rate on those wireless modems and such fall right in the HF band. You've already listed what I've tried: antenna orientation.

However, most of those things have a variable power output. You can "log in" to
them via a web interface; point your browser to their IP address and you can perform administrative functions including adjusting the output power.

One of two things will happen: Increasing the output power may cause the data rate between your computer and the router to increase, pushing the RFI higher in the HF spectrum. Or, you may find that using the minimum power possible you can reduce the interference level. I guess what I am saying is try changing it and see what happens.

The one I am using right now is an AT&T wireless DSL modem made by 2Wire.

Good luck,

Al W6LX

1068. feedback requested from pickup truck owners on antenna brackets

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-11 18:51:25 UTC
From: Radio_Dick <rspost@mail.com>
Message-ID: <cffb3cfa-946d-4fdb-8198-0dc8014da052@l64g2000hse.googlegroups.com>
Source record: 23542

Greetings,

I'm looking for pickup truck owners who would be willing to provide measurements for, and feedback on, three prototype heavy-duty brackets for mounting HF antennas to pickup truck beds.

The brackets are: (1) front bed wall bracket with lay-back feature for large screwdriver/motorized antennas; (2) stake pocket bracket for large antennas; and (3) long bracket for multiple antennas that extends across the entire width of the bed and is attached to two stake pockets.

Your input would help me to obtain information on a variety of makes and models of trucks, and to get feedback on what may work well, or not, on your particular truck. I've gotten some information from manufacturers' web sites, but additional "real world" information is important for good product design!

If I get sufficient measurement information, I'll post it on my web site Downloads page as it may be useful to others.

If you would be willing to provide information, please click on this link (http://www.repdesign.us/gpage8.html) to my web page which has the measurements I'm looking for and descriptions with diagrams of the three bracket designs. On this page I also have a link to an on-line Feedback Form that you can use to provide as much or little of the information as you like. You can also email or phone me with the information if so desired. My contact information is linked on this page as well.

Thanks in advance to those who would be willing to provide information, and it's much appreciated!

73,
Dick Post, N7EMW

Sonny, you seem to be using the Inverse, of the Inverse Square Law
here.... the Farther the source is from the receiver the LESS power
reaches the receiver, not MORE. It goes Down, by the SQUARE of the
distance, not up. You also don't get ALL of the 300 Milliwatts
going into your head as the antenna is semi Omni-directional and
only about 120 degrees of the 360 degree transmitted signal will
intersect with your head, and another maybe 10 degrees with you hand.
Better go back and do the Sums, AGAIN, or leave it to folks that
passed Jr. High School Math, and High School Physics.

BUT we were talking about Handheld Cellphones, and these typically have
a Maximum RF Power to the antenna of 300 Milliwatts, which is then
Telcommanded Lower by the Base Station, depending on Base Stations
Received Signal to Noise Ratio. There are a few, up to, 3 Watt Digital
Cellphone Subscriber Units, but they ALL have external Antennas, and
these antennas are NOT designed to be attached to your HEAD....
Apples and Oranges......

EXACTLY! That is why the further the source is from the
"receiver/your-skull" the further the sources power must be increased to
maintain the same field-density! You got it!

Inverse Square Law in action! Or, ~2:4 ratio--every doubling in
distance requires the fourfold increase of the sources output to
maintain field density -- what part of my posts must I "rewrite" for you
to obtain that meaning from them?

Regards,
JS

Or, to simplify, once again, 300mw@6mm ~= 1.288KW@38.4cm ... re-read my posts, you (that is your "name", right? <grin>) missed it!

However, I have rethought those distances, since, I now realize the antenna in the phone is much closer to my skull than I had first thought; here is the "new breakdown":

3mm@300mw = 6mm@1.2W
6mm@1.2W = 12mm@4.8W
12mm@4.8W = 24mm@19.2W
24mm@19.2W = 48mm@76.8W
48mm@76.8W = 96mm@307.2W
96mm@307.2W = 19.2cm@1.288KW

19.2cm ~= ~7.5-inches

Anyway, point is, when I use my cell phone without a headset, that spot on my head, directly under the cell phones' antenna, is getting the same exposure as it would get from a 1.2288KW source utilizing the same antenna, and at a distance of 7.5 to ~15 inches from my head! (realize the importance of that 19.2cm/7.5-inch vs. 1.2288KW figure!)

Anyway you cut that--it ain't pretty! My wife, frequently, makes 2+ hr calls to family! Did that help?

Now, anyone want to explain the "yellow journalism" in that to me?

Regards,
JS

Three or more follow-ups, by me, heck, with you around, it will, most likely, take many more than that!

Some here are just "slow on the uptake", then some like you like tossing suspicion to hard data around and disinformation (even though cloaked as "cryptic comments.")

Pull up a chair, get a drink and relax--we may be in for that "ride" you are threatening ... (i.e., clarifying/defensive posts.)

Did I mention the fact that, those with few/or-no friends are not in danger, much, from cell phones either? <grin>

Here are complete disassembly instructions for my phone, the one in question. The antenna IS NOT where the "kid" (well, he was much younger than me <grin>) at "the cell phone place" told me it was ... indeed, it is UNDER MY HAND while I hold the phone! (actually, between head and hand!--nice for efficiency, huh?--probably drives it towards that 300mw all-the-more-quicker!) (so much for "placing the antenna logically!")

Now I am thinking the area of highest exposure, on my head, is my cheek/nose/upper-gum-area ... and, this makes the area of the phone containing the antenna further from my head; and the equivalent distance to a 1+KW source is much further, feet away instead of inches ... but, I would be hesitant to remain in my garage with I in one corner and an "omni-directional, Cooking Band(CB), frequency generator" of 1+KW in the other corner! -- But then, that is just me ... (and the phone is a MUCH closer danger than that ...)

That all changes little in my mind. Although I really do not sweat HF RF, much, I would still be hesitant to expose myself to levels of it of those intensities in question FOR the length of time(s), and that frequently, as is in question, however, if the need arouse, I'd probably do it ... at VHF/SHF I WOULD NOT! And, especially to those freqs in the CB Bands (Cooking Bands <grin>)

It would take "extreme motivation" for me to ignore the "prudent man rule"; but, even that is possible ...

I am sorry if this has been a source of "yellow journalism", to me, they seem honest mistakes/bad-data, but I admit, the mistakes do not help ... my original point seemed "so harmless", "be prudent/cautious" :-(

Tell you what, consider all this just "One Mans' Opinion", gather your data and then you decide ...

JS

I am correcting an error from previous postings, I suspect this to-be/might-be the "yellow journalism" you complain of ... I was in error on the antennas' placement within the phone ...

I now consider the "clear and present danger" of the cell phone, to my brain (frontal lobe(s) now), to be an equiv. to a 1.2288KW source at a distance of 448cm/~176-inches/~14-ft. from my frontal lobes ... a "distance error" of magnitudes!

But, IMHO, a still a REAL, CLEAR AND PRESENT, danger ... glad you made me improve the accuracy of the data I was offering ... THANKS!

I did not compute the dangers to my eyes, from an equiv. source ... the eyes are thought first to go, right? LOL!

However, the placement of the antenna has introduced a new high exposure areas, my nose/cheek/lips/upper-gum/hand ... and the placement means the phones antenna is completely engulfed in a "shield" of my body ... undoubtedly lowering that antennas' efficiency and forcing it towards max. power all the more quicker ...

If there are inaccuracies here, in this post, you will have to point them out to me so I can see them ... and this is only one phone ... where is the antenna in "all the others?"

JS

Perhaps I would be better served by my argument that a lot of people are selectively stupid. They pick and choose what they find dangerous. They hurtle towards each other on the highways often at relative speeds of 160 miles per hour, while carrying tanks of liquid so flammable as to be almost explosive. Yet not a thought is given to the gasoline in their tank, except perhaps to the cost.

> Again, this sort of logic (sic) merely perpetuates the nonsense Brett
> Gump loves to forward through these threads.

Perhaps a simplification of my argument is in order again.

People are very selective about what they fear. Sometimes they embrace a technology that is no less dangerous than another action that they would never do.

Strictly speaking there is a difference in the tissue between the exposed areas. Is there a difference? I don't know. That's another test.

> This is the absurdity of Brett's Yellow Journalism research and how
> the topic has drifted from the technical to the superstitious. Mike,
> do you care to respond to my technical comment of 3 days ago, or is
> this deviant speculation really that more relevant to anything?

Sorry Richard, I didn't see that post. I might google it up when I get a chance.

But I detect an interesting drift to your reply. How much of your disagreement with me is due to my speculation on how people are remarkably inconsistent in their acceptance of risk, and how much is the disagreement because for once, I am in agreement with Mr. Smith?

This is in no way an argument for elimination of cell phones. It is an argument that we should not have them hanging off the side of our heads for hours. Even my XYL will chat with a friend for an hour plus on her cell. Makes me cringe. My own personal rule is no more than a minute, and I stick to it.

My arguments for exposing one's offspring are specifically designed to be ridiculous upon reception. No one in their right mind would ever expose their children like that, nor their husbands, wives, etc. But to the brain tissue, an exact analog could be delivered. Yet why would we not do it? The answer is because we shouldn't.

My point has been proven. I'm a little surprised that it was you who provided the proof.

Fields superpose, numbers add, and power is the rate of change in energy.

> When fields superpose, they still must obey
> the conservation of energy principle, i.e. the total energy
> before the superposition must equal the total energy after
> the superposition.

It's almost as if you think that if you don't always point it out,
energy won't be conserved! :-)

> Given two RF waves in a transmission line and the phase angle,
> A, between the two electric fields, the following Power equation,
> published in QEX, gives us a valid method of "adding" two powers.
>
> Ptotal = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

According to fig. 7.1 in Born and Wolf, that's useful for showing how
light intensity varies as a function of phase, and hence position. It's
just that there's no valid way to multiply by the cosine of the angle
between two scalars.

Maybe wave problems are best solved using waves.

> The last term is known in optics as the "interference"
> term, positive for constructive interference and negative
> for destructive interference. Angle A, the phase angle
> between the two electric fields, determines the sign
> of the last term and thus whether interference is
> destructive or constructive.

(A+B)*(A+B) = A^2 + B^2 + 2AB

Must the first order term (2AB) in such equations always be referred to
as "The Interference Term", Cecil? Doing so seems to impart a greater
level of importance to it than to the other, unnamed terms in the
equation. The factored form must then be least important of all.

Beats, interference, and modulation are fundamentally the same
phenomenon. There's no need to get all worked up about one of them in

deference to the others, just as there's no need to worry about there being a node for every antinode.

You are pretty confused. The angle is between the electric
field intensities of the two waves being superposed.

> Must the first order term (2AB) in such equations always be referred to
> as "The Interference Term", Cecil?

From "Optics", by Hecht, 4th Edition, page 387 & 388:

"I12 = 2<E1*E2> ... and is known as the interference term."
E1 and E2 are electric field intensities. * is the dot product.
<> indicates a time average value.

"The interference term becomes I12 = 2*SQRT(I1*I2)cos(delta)"

Hecht calls it the "interference term" and I am only quoting
him.

The correct plural form of Antenna is Antennae.
I you prefer Antennas fine I have been told recently by an Elmer that
this was the correct term.
The question here is not grammar but staying on topic for this forum.
I'm not trying to cause an argument we have different forums so
everyone can have there say.
Let's just stay on the topics of each forum.
73's :)

Aye Captain ... do antennas exist as an island?

What antenna can function without parameters?; A feed-line, a rig to drive it, a media to propagate through, an operator to operate it, inherent dangers, neighbors to complain of it, etc.? <grin>

I think you know that I'm just pointing out the problem inherent in using a valid equation in the way you describe without considering the many assumptions being made. It led you, for example, to write that there is a 4th mechanism of reflection - even in violation of Maxwell's equations! Do you still believe that interference actually moves power from one place to another? It is that kind of nonsense that amateur radio would be better off without.

I can tell you HAVE been doing your research! <grin>

THIS:

* (pl., antennae). Pair of segmented appendages (feelers) located on
head and sensory in function (Fig. 1).
www.sidney.ars.usda.gov/grasshopper/ID_Tools/F_Guide/Glossary.htm

* One of a pair of sensory appendages on each side of an insect's head.
www.frankstehno.com/sagemesa/guide/terms/aterms.htm

* (plural antennae) The sensory organs on the head. Stag beetles have
two antennae or 'feelers' with a characteristic shape at the end, which
is the same for all the beetles that belong to the Lucanidae family. It
is with their antennae that stag beetles pick up important pheromone
signals.
maria.fremlin.de/stagbeetles/glossary.html

* Antennae (singular antenna) are paired appendages connected to the
front-most segments of arthropods. In crustaceans, they are biramous and
present on the first two segments of the head, with the smaller pair
known as antennules. ...
en.wikipedia.org/wiki/Antenna (biology)

* A feeler organ on the head of an insect, crab, or other animal; A
device to receive or transmit radio-frequency signal by converting
electromagnetic radiation into electrical signal; The faculty of
intuitive astuteness

Here's a quote from my energy article:

"Note that the author previously used the word "reflection" for both
actions involving a single wave and the interaction between two waves.
Now the word "reflected" is being used only for single waves and the
word "redistributed" is being used for the two wave interference scenario."

Nowhere in my present article do I say there is a 4th mechanism
of reflection. Why do you continue to incessantly harp on past
semantic blunders that were corrected years ago?

> Do you still believe that interference actually moves power
> from one place to another?

Do you ever stop beating dead horses? :-)

Since I stated in my article that power doesn't flow, you are just
once more bearing false witness. Maybe you should have that burr
under your blanket looked at by a competent veterinarian. :-)

I said that the redistribution of energy, which necessarily obeys
the conservation of energy principle, is associated with a wave
cancellation interference event. I never uttered your false
statement that "interference moves power". Here's what I said:

"The term "power flow" has been avoided in favor of "energy flow".
Power is a measure of that energy flow per unit time through a
plane. Likewise, the EM fields in the waves do the interfering.
Powers, treated as scalars, are incapable of interference."

Yet, a couple of times a year just like clockwork, you accuse
me of saying that power moves (which I have never said). One
wonders what drives your never-ending vendetta obsession.

Here is the definition that I am using for RF "interference"
adopted from "Optics", by Hecht:

RF wave interference corresponds to the interaction of two
(or more) RF waves yielding a resultant power density for
the total wave that deviates from the sum of the two power
densities in the superposed component waves.

It is simple physics to realize that (V1+V2)^2 is not usually equal to (V1^2 + V2^2). When they are not equal, interference has occurred. Why do you have such a problem with such a simple concept?

In a transmission line, the power equation indicates exactly by how much the resultant power deviates from the sum of the component powers. The magnitude of that deviation from the sum of the component powers is called the "interference term" according to Hecht.

Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)

'A' is the angle between the V1 and V2 voltage phasors.

I'm curious how you arrived at the "correctness" of antennae.

Miriam Webster's Collegiate Dictionary, Eleventh Ed., lists both plural forms. Random House Webster's Unabridged Dictionary, Second Ed., explicitly states that antennae is plural for the appendages on insects, and antennas is plural for the electromagnetic device. These different plural usages are by far the most common in my experience. I only occasionally see "antennae" to describe radio antennas, mostly in very old texts or when used by an academic -- or rraa poster -- trying to emphasize his distance from the hoi polloi.

Your reference for "correctness" didn't happen to be a zoology text, did it?

Roy Lewallen, W7EL

Source record: 23372

One additional point.

On my bookshelf are:

Antennas (Kraus), _Physical Design of Yagi Antennas_ (Leeson), _HF Antennas for All Locations_ (Moxon), _Antennas and Transmission Lines_ (Kuecken), _Radiowave Propagation and Antennas for Personal Communcations_ (Siwak), _Lines, Waves, and Antennas_ (Brown et al), _Antennas and Waves_ (King and Harrison), _Transmission Lines, Antennas, and Wave Guides_ (King et al), _Directional Broadcast Antennas_ (Layton), and _TV and Other Receiving Antennas_ (Bailey).

Other books have "Antennas" in chapter titles, e.g., in _Antenna Engineering Handbook_ (Johnson) we find "Loop Antennas", "Small Antennas", "Microstrip Antennas", "Leaky-Wave Antennas", and so forth.

I don't have a single text with "Antennae" in the title, chapter heading, or body. But then, I don't have any entomology texts at all.

If "antennae" is to be the "correct" plural for radio antenna, an awful lot of very well known authors and publishers need to be made aware of it.

Let me try this then: Do you still think that interference is what
moves ENERGY from one place to another?

> "The term "power flow" has been avoided in favor of "energy flow".

> Yet, a couple of times a year just like clockwork, you accuse
> me of saying that power moves (which I have never said). One
> wonders what drives your never-ending vendetta obsession.

Note that the reason the author included the disclaimer about "power
flow" was because the term "power flow" had not been avoided by said
author in this newsgroup, in an argument which must have gone on for 6
weeks. In fact, it was a point that was never actually conceded.
Rather, thusly, he "avoided" conceding it. (Reminder: Now you come back
by mentioning how Poynting vectors show how much and in which direction
the power is flowing.)

> It is simple physics to realize that (V1+V2)^2 is not usually
> equal to (V1^2 + V2^2). When they are not equal, interference
> has occurred.

Well, 8th grade algebra is supposed to help us realize that (V1+V2)^2 is
not equal to (V1^2 + V2^2). But the fact that (V1+V2)^2 is equal to
V1^2 + V2^2 + 2V1*V2 doesn't depend in the least on whether
"interference has occurred", Cecil. That was the whole point of my
comment about it.

> In a transmission line, the power equation indicates exactly
> by how much the resultant power deviates from the sum of the
> component powers. The magnitude of that deviation from the
> sum of the component powers is called the "interference term"
> according to Hecht.

You'd think it would be enough for someone to throw out the whole idea
of "the sum of the powers" once and for all. But no. The inclination
instead is apparently to keep refining one's epicycle formulary. Hecht
makes no such connection between 'power' and 'interference', Cecil. And
why would he? There isn't one.....except in certain amateur radio

articles and newsgroup postings.

> Ptotal = P1 + P2 + 2*SQRT(P1*P2)cos(A)
>
> 'A' is the angle between the V1 and V2 voltage phasors.

...and NOT between the two 'powers'. Still, it's a very useful expression for finding a quick, albeit simplified solution. That is after all its intended purpose.

Hey, the good ole' boys sent me another, unsolicited, email <YEA!> ;-)

I guess they expected me to post it here, as a follow-up; OK, I will:

-----BEGIN PGP SIGNED MESSAGE-----
Hash: SHA1

As a routine procedure, significant numbers of article rejections by a
given submitter are reviewed by our Appeals Board, and a determination
is made whether that individual requires administrative action. Such
actions could include warnings, suspensions, or in extreme cases such as
uncooperative repeat offenders, a permanent ban from our newsgroup.

Our Appeals Board has decided to assign a temporary suspension from the
rec.radio.amateur.moderated newsgroup for a period of 60 days from the
date of your last article rejection (July 29th, 2008). During this
time, your article submissions will be automatically rejected without
moderator review. We may also choose to report continued rejected
submissions to our newsgroup to your ISP as unsolicited, harassing,
communications with our team. Your suspension will be lifted on or
about September 27, 2008. We caution you to take our feedback under
consideration, and incorporate it into any future submissions after the
suspension is lifted.

Your rejected articles, and rejection reasons, are given below. We have
also considered a message that was sent to our administrative contact
address, also included below. Our recommendations to you going forward
include:

- There is no need to test the moderation system, or the moderators.
We are in positive control of the newsgroup, and are willing and able
to reject any articles that do not meet our charter and posting
guidelines. A couple of the articles that you have submitted, and
were rejected, were obviously rejectable by the standards of nearly
any moderated newsgroup, so we see no reason why they were submitted
except as a test or provocation.

- Our newsgroup is about amateur radio, not about off-topic discussions
of individual personalities, nor complaints or criticisms or
speculation about moderators and moderation decisions. To allow this
off-topic content would reduce our newsgroup to the state of some of

the presently-ruined and unusable unmoderated newsgroups (newsgroups which we notice that you will not even post to anymore).

- The moderation team is willing to positively recognize acts of good faith, and consider mitigating circumstances when evaluating histories of article rejections. These include submitters making recommended edits and resubmitting articles, as well as utilizing our appeals process. The Appeals Board, a team of moderators separate and independent from the team that reviews article submissions, is always willing to fairly consider civilly-stated, original appeals and complaints sent to our administrative contact E-mail address (given below). We are not impressed or swayed by uncivil, bad-faith, methods of complaint, including public ad-hominem attacks against the moderation team in other forums, and E-mailed ASCII-art representations of obscene hand gestures.

- We ask that any submitter to our newsgroup engage in some reasonable amount of self-reflection as to the purpose and end-goals of their participation. Are you truly engaging in honest, good-faith efforts to convince others of your point-of-view, possibly to help make the world (or our small part of it) a better place? Or is the newsgroup merely a target of convenience for your abuse, anger, grudges, prejudices, and attempts at retribution that would be socially unacceptable, and punishable, elsewhere? Are you seeking to use public forums such as ours for personal entertainment from "stirring the pot" with obvious trolling and flame-baiting? Unmoderated newsgroups may have to tolerate such behavior, but moderated newsgroups such as ours do not. We will take decisive action to protect our newsgroup for the benefit of those who do wish to participate constructively, and not be insulted, harassed, threatened, or otherwise abused by individuals who are apparently not interested in constructive participation.

We do sincerely hope that after the suspension is lifted, you will have either chosen to break bad habits by leaving the newsgroup permanently, or be able to moderate your habit and participate productively in on-line forums such as ours. If not, the next likely action of ours will be either a much longer suspension, or possibly even a permanent ban.

- --

The OED lists 'antennas' as an acceptable plural for radio aerials, (but not insect feelers)

I concede the point of grammar ok?
The original point was not whether the correct plural form of antenna
is antennas.
One antenna and two antennas ok?
This forum is about antennas not songs that was my point.
Why can't we stay on topic?
I'm a new Ham and want to learn more about Antennas.
I have been an Amateur for 4 months and went from Tech to Extra in 2 ½
months aced all 3 tests.
My interest is becoming the best Amateur Radio Operator I can be.
Along this line I'm looking for help, at age 64 it is just as important
to me as it is to a 10 year old Amateur.
73's :)

To the best of my knowledge, I addressed all of your objections
in a revision to my energy article which was done many months
ago. The reasons for your objections don't even exist any more.

> Note that the reason the author included the disclaimer about "power
> flow" was because the term "power flow" had not been avoided by said
> author in this newsgroup, in an argument which must have gone on for 6
> weeks.

But that argument happened many, many years ago. You convinced
me that power doesn't flow. I respect the fact that it is a
commonly accepted concept defined in "The IEEE Dictionary",
rampant within every power company, and accepted by many
members of this newsgroup.

If you will check back over the years, you will find a posting
of mine where I said the dimensions of power flow would be
joules/sec/sec which doesn't make any physical sense.

> But the fact that (V1+V2)^2 is equal to
> V1^2 + V2^2 + 2V1*V2 doesn't depend in the least on whether
> "interference has occurred", Cecil. That was the whole point of my
> comment about it.

Yes, and you are still wrong according to Hecht. If the
interference term in the power equation is not zero,
(V1^2+V2^2) does not equal (V1+V2)^2. In the special case
where (V1^2+V2^2) = (V1+V2)^2, the interference
term is zero, i.e. zero interference.

Please reference page 388 in "Optics", by Hecht, 4th Edition.

> Hecht
> makes no such connection between 'power' and 'interference', Cecil.

But Hecht certainly makes a connection between 'power density' and
'interference'. It is a trivial matter to convert the power density
irradiance equation to the power equation by multiplying by the
cross-sectional area of a transmission line.

The units of irradiance (power density) are joules/sec/unit-area.

Multiply the irradiance equation by the unit-area of the coax,
e.g. 1 in^2, and you get joules/sec = power which is what a

Bird wattmeter indicates.

If you want, you can convert the Bird wattmeter reading to
irradiance by dividing by the cross-sectional area of the
coax.

>> 'A' is the angle between the V1 and V2 voltage phasors.
>
> ...and NOT between the two 'powers'.

Nobody has ever said there is a phase angle between two powers
yet you persist in that false strawman implication.

Well then, inundate us with your exuberance, recently aquired knowledge
(on topic of course, and all of your questions just screaming for
answers (on topic of course)--your "speculations" of antenna(s) (or
possibly, in your case, antennae) could also, possibly, be appreciated
(on topic of course!)

For the rest of us bored "news-groupers", well ... I know you find it in
your heart to forgive me/us/them. ;-)

As far as grammar goes--I am not big on it; if I can "get your 'Jest' "
(yes, a bit of pun), I'll be satisfied ...

Regards,
JS

Dear Howard KJ4DIY:

Your goal is commendable. An excellent start is to read the ARRL's Antenna Book. It will teach and inform about most of the breadth of antennas and their issues. Depth of understanding may be found in Kraus' Antennas (3rd Edition), which is an excellent textbook with examples. However, it is a college level text. Success in your quest. 73, Mac N8TT

Well, Hecht and I both understand the 8th grade algebra, and I don't
disagree with him. How then could he disagree with me? I think that's
the symmetric equality property. :-)

One possible way to resolve the apparent dichotomy would be to suppose
that you misunderstand what we are each saying.

Which of course explains how it is that your answers come out correctly.
I believe I already mentioned that it does (obviously) produce correct
answers, given all the underlying assumptions are correct.

By the way, what assumptions are you making?

> If you want, you can convert the Bird wattmeter reading to

It's hard to imagine how a simple, mutually agreed upon statement of
fact could be construed as a "false strawman implication", but there it is.

Yes, exactly as it has been for the past six months since
I revised my article. In less time than it takes to condemn
me for saying something in the far distant past, you could
have just read my article. Here's the half-year old footnote
from my article.

[10] Revision 1.1, Feb. 20, 2008 - In the original version, the
redistribution of energy due to wave cancellation was dubbed a
"reflection". W5DXP has dropped that designation in favor of a
"redistribution" as described by the FSU web page. The word "reflection"
is reserved for describing something that happens to a single wave when
it encounters an impedance discontinuity. The word "redistribution" of
energy is adopted for describing what happens to the energy in canceled
waves. In like manner, since interference can occur with or without wave
cancellation, any reference to interference as the cause of the
redistribution of energy has been removed.

>> You convinced me that power doesn't flow.
>
> Thank you, Jesus.

That was at least eight years ago, Jim. What is wrong with
you? I have no doubt that six months from now, you will again
be accusing me of believing that power flows. You seem to be
suffering from dementia.

> Which of course explains how it is that your answers come out correctly.
> I believe I already mentioned that it does (obviously) produce correct
> answers, given all the underlying assumptions are correct.

However, correct answers don't seem to be enough for you.
You seem to be looking for a stone tablet handed down from God.

>> If you want, you can convert the Bird wattmeter reading to
>> irradiance by dividing by the cross-sectional area of the
>> coax.
>
> Wouldn't I first have to buy into the idea that power is flowing through

No, irradiance, like power, doesn't flow. If you don't know
that, that's probably the source of your confusion.

> It's hard to imagine how a simple, mutually agreed upon statement of
> fact could be construed as a "false strawman implication", but there it is.

Your multiple unethical attempts to imply that I said power
has a phase angle is more than obvious to everyone.

Look if you really want the RF evaluation done, I need to charge you for it. I could show you where you are wrong in your calculation, verify what is correct and you can do what you want with it. It will cost you even more if I have to actually measure the power bandwidth and density of the actual unit.

You spoke earlier about widespread corruption and no trust beyond your fear. I can understand suspicion, but your fear is largely based on the unknown. It might help you to consider that manufacturers are largely motivated by greed, so it would be absurd to worry that they would spend the extra money to exceed the FCC specifications for maximum output, although I'm sure that there are individuals who would spend the extra money for an amplifier. I would suspect that sales would get their money and the customer would be sent to the complaint department to get their money's worth and the responsibility would fall.

Ahhh, you are an idiot!

You will have to excuse me. Yanno, sometimes you just run into that rare circumstance where, at first the person "seems normal." After a bit of dialog, however, you realize "there is no one home ...

1) They (cell phones) DON'T exceed the maximum allowed--and THAT IS SCARY! (1.6W per Kg ... how much does your head weigh?)

2) An amplifier would do you little good unless you could also increase the output on the cell tower ... but then, I don't like burnt toast! ;-)

3) The "damage" we "debate" is of such a nature, it could only be found it statistical studies--all studies to date are flawed ...

4) I expect "this problem" to take longer sorting out than the the tobacco problem/danger. How many deaths from tobacco alone?

5) Massive corruption, greed and loss of trust, that is in question? What else do you call it when the will of the people is constantly ignored; and when all-else-fails, the courts are called in to make a decision that the will of the people is NOT constitutional! (Rather illogical when the constitution takes justification from "we the people ..." I believe that same justification is used in the California law.)

6) New Orleans has still not recovered, despite "federal help", many are still without homes--google it! If it were in another country, we could have emergency supplies anywhere in the world in a matter of days and begin helping rebuild in a matter of weeks ... more goes on in Oz than meets than eye ... the terrorists only need to walk across the border--good for us they are too stupid to figure that out ... I guess.

PLONK!

Welcome.

I've been licensed for 15 years and passed Extra last year. Never aced anything. My scores belong in the Witness Protection Program.

ARRL Operating Manual is good source for beginners. www.arrl.org/catalog and http://www.arrl.org/catalog/index.php3?category=Operating

Also, http://www.arrl.org/catalog/?item=1018#top for the ARRL Handbook. (Can't tell why it's listed separately.) Not everybody likes the ARRL. I do.

Much useful info shows up in the newsgroups. Just keep your mental filters switched on.

That is the age old question with the newsgroups, Howard.

> Iï¿½m a new Ham and want to learn more about Antennas.

It is possible that you are fairly new to Netnews. While a place to
learn and teach and have fun, it is also largely unregulated. So we get
a fairly high noise to signal ratio.

In addition to the off topic forays, many of our more accomplished
members have favorite topics that can go on for quite a while, long past
any real reason, just tit for tat comments.

The best strategy is to just accept that there will be off topic and
run-on threads in the newsgroup, and either filter or otherwise ignore them.

That in no way means that you can't tweak someone once in a while! hehe

> I have been an Amateur for 4 months and went from Tech to Extra in 2 ï¿½

A general rule of thumb is to post a question, and the first few
answers will be the relevant ones. After that all bets are off.

Regarding the age thing, It is an excellent hobby/avocation for a
retiree or young ham. I got into the ARS later than some, at 46 years
old, but it's all good.

You might want to try out rec.radio.amateur. moderated also.

I was joking about actually putting an amplifier on any wireless device that you can put in your pocket and runs on batteries. But I guess I have to be very careful with the ignorant and superstitious, because an offhand quip might be taken to heart and grow to be a religion like your exposure rant. You call them "cell towers" because it is your boogie man. You probably haven't even been on a tour to a transmitter site.

Everyone check this out:
http://en.wikipedia.org/wiki/List_of_fallacies

Read the section on "Red Herring fallacies"

Your numbers are all wrong so you call me an idiot. These newsgroups are googled and will probably be around for a while. Your conclusions based on your own erroneous suppositions won't make me an idiot. But you obviously have an environmental liberal whacko agenda to promote or you would produce your evidence.

My 30 year + observations of a community of professionals (and not so professionals) is the only statistical evidence I need to prove your dog can't walk because it has no legs.

If you want to do some good, why don't you rant about X-ray exposure from CRT's and why everyone should get rid of them in favor of LCD's for computer monitors, because I guarantee it is way more a health risk than little wireless devices.

You are correct that California is way AFU, but you don't know the half of it. Until you do, the same mistakes will be made when it comes to your town, because you are lock-stepped to belief systems that reject reality, so you will continually lay the blame for your error elsewhere until it has you by the throat.

Many years ago, five or more, I agreed with you that power doesn't flow. Yet, more than a dozen times in the ensuing years, you have accused me of believing that power flows. I denied it every time, yet you did it again this very month.

Many months ago, I revised my energy article based on your inputs. Yet, you continue to accuse me of promoting a "4th mechanism for reflection caused by interference".

Incidentally, whether interference causes reflections or not certainly depends upon the definitions of "interference" and "reflection" which seem ill-defined to start with.

Whether your rraa behavior is deliberate or not, it points to a personality disorder of some kind. I cannot find "glutton for punishment" in the "Diagnostic and Statistical Manual of Mental Disorders" but maybe you can plead 302.83 or 302.84.

Not everything is an accusation, Cecil. Please stop with the
melodramatics act. You wrote that bit about the 4th Mechanism of
Reflection in your paper against every bit of advice I had given you for
months. Buck up and take responsibility for your yourself for once.

I spent 5 years in front of large CRTs while wearing a radiation monitor. When no one showed any sign of radiation the monitoring ceased. Did pick up some radiation from unrelated sources, but nothing from the CRTs.

Probably getting more radiation from the ionization smoke detector on the ceiling of my den! Not to mention all the natural sources - bananas for example.

One more time: "[10] Revision 1.1, Feb. 20, 2008 - In the
original version, the redistribution of energy due to wave
cancellation was dubbed a "reflection". W5DXP has dropped
that designation in favor of a "redistribution" as described
by the FSU web page. The word "reflection" is reserved for
describing something that happens to a single wave when it
encounters an impedance discontinuity. The word "redistribution"
of energy is adopted for describing what happens to the energy
in canceled waves. In like manner, since interference can occur
with or without wave cancellation, any reference to interference
as the cause of the redistribution of energy has been removed."

This problem, IMHO, demonstrates a 1:1 relationship to the problem of cell phones and why any harm they might exhibit would be "masked" by financial, power and special/political interests.

http://newswire.ascribe.org/cgi-bin/behold.pl?ascribeid=20080815.130545&time=14%2013%20PDT&year=2008&public=0

and is VERY similar to how studies such as the one mentioned here:

http://www.rense.com/general26/2yrs.htm

are being ignored.

But then, some will attempt to dismiss all this to "environmental wackos"--"Darwin Awards" coming soon!

"IEEE Spectrum" has had a couple of articles on tumors
caused by cell phones. They don't seem to be life-
threatening but maybe "where there's smoke ..."?

1. Can cell phones promote brain tumors the INTERPHONE study?
Lin, J.C.; Antennas and Propagation Magazine, IEEE
Volume 47, Issue 2, April 2005 Page(s):137 - 138
Digital Object Identifier 10.1109/MAP.2005.1487813

2. The risk of acoustic neuromas from using cell phones
Lin, J.C.; Antennas and Propagation Magazine, IEEE
Volume 47, Issue 1, Feb 2005 Page(s):183 - 185
Digital Object Identifier 10.1109/MAP.2005.1436270

Cecil:

I simply find it "strange", that the presumption that exposure to forms of radiation (RF in this case) is always considered safe until proved/proven harmful. The same goes for chemicals not existing in nature and to which the human body (or any biological organisms for that matter) has never been exposed. It seems all which is needed is to chant a "paranoid/wacko" mantra and such forms of thought are naturally generated in the human mind. The presumption, so generated, seems to be, "If we have never seen it before, if we have never been exposed to it before, maybe it is actually good for us!"

I mean, is this prudent thinking/behavior? Am I the only one to think the proof should rest with those introducing the potential harmful exposure/materials and their SAFETY--rather than those being exposed having to prove its' harm in order to effect their own safety?

If you look at the parallels between how tobacco was allowed to continue, without even a warning and for such a lengthy period, it all revolved over disputing studies/good-science which kept pointing to the dangers ... indeed, into the 70' and well beyond, the warning that "smoking was bad" was met with those chanting the myths of flawed studies ...

What truly amazes me is the fact that simple "safeguards" are available to vastly reduce risk (at least with cell phones.) What has become so

ingrained into our thinking/media which can make otherwise responsible men and women so irresponsible ... money, greed, corruption, insanity?

Someone here has thinking that is "a bit off", if it is me--I only pray rationality will come home ... I will continue to "re-think my thinking", maybe I will eventually see it ... until then, I do keep abreast of the "Rush Limbaugh Manta"--"Things are Good and Getting Better, don't trust your eyes, mind and thinking--they lie!" It simply does NOT motivate me "To Believe!"

I am willing to listen to any studies which find that cell phone radiation is making me smarter, handsomer, wittier, richer and more sexually attractive to the ladies, etc. ;-) Just show me some honest, unbiased studies which deal on REAL SCIENCE ... look at Love Canal in New York and the battle to prove, legally, that these chemicals being dumped into the environment were harming/killing people! ... how many examples before one chooses to error on the side of caution?

Let me give you a "hard case example", perhaps 99%+ of the snakes in the world are NOT POISONOUS--would I be prudent to consider the next snake I see non-poisonous and of NO danger? I think not ... heck, just a relatively "harmless bite" will get my attention! (not to mention the danger of infection.)

Regards,
JS

Most of the people around here who have their heads glued to
cellphones, constantly, don't have enough brains to support
tumors successfully, anyway, so the problem is non-existent.

Source record: 23407

This is a very general question. I'm looking for a very 'general'
answer, nothing particularly specific or 'brand' oriented.
What is a good listening or SWL antenna? Range would be from the
broadcast bands up through VHF/UHF. The 'attributes' of bigger and
higher come to mind, but how about something more than that?
- 'Doc

Keeping the answers sort of general, not too technical for the average
person who knows little about radio stuff.

For general SWLing, it's hard to beat a twinlead
center-fed dipole. For VHF/UHF, a discone is probably
a good choice. (VHF/UHF is not SW)

Wrong again. The base fluid of blood is very like sea water, and with
good reason. The salt and other solute contents are essentially the
same between blood serum and sea water.

Unfortunately, your radio knowledge seems to be as inadequate as your
biology.

Indeed for VHF-UHF a discone is reasonably universal.
For MF-HF a twinlead centre-fed dipole is great but one should include a matching box (tuner if you like) to get the best out of this antenna,to connect it to any receiver (usually having an unbalanced antenna connection)
Otherwise a length of 'free-hanging'wire will be good enough .

I took a $40 Radio Shack SW radio to South Africa last October for several weeks. It had a standard 3 foot extendable whip that couldn't hear short wave until I clipped some wire-wrap wire onto the end and lobbed the ww wire up onto the roof of our cottage (while sitting outside in the evening or the morning). All-in-all about 20 feet of wire with a nickel taped to the end to help tossing it. I got more stations than I knew what to do with. No additional wire was necessary for VHF (FM), of course, and UHF would have only needed the whip collapsed to match (if UHF were available for that radio).

This:

"First off, while both contain many of the same salts, concentration of dissolved particles in blood is very different from that in seawater. The primary constituents of both are sodium and chlorine (which together make up common salt, NaCl), but seawater has three times as much sodium and five times as much chlorine per unit weight. Hardly the same. Furthermore, it contains eight times as much calcium and fifty times as much magnesium."

Come to think of it, your Google-ing abilities may be as wanting as your logic abilities ...

So, a hint, if blood had as high a concentration of salt as sea water, a person might be able to drink it and survive ... or, the osmotic pressure of blood is around 300, that of sea water is over 1000 ...

Well, come to think of it, that won't do now, will it?

I mean your education in biology is probably just as lacking as in all the other sciences you have demonstrated here ...

This:

"Human blood plasma has an osmotic pressure of about 290 mOsm and water from the open ocean has an osmotic pressure of about 1010 mOsm. This indicates that there is much more salt in sea water than in human blood plasma and also that there is less pure water in a liter of sea water than in a liter of plasma. Just as ions diffuse from areas of high concentration in a solution to areas of low concentration, so do water molecules diffuse from areas of high water concentration (= low osmotic pressure) to areas of low water concentration (= high osmotic pressure). In considering this it is well to remember that salt added to water lowers the water concentration of the resulting solution. When water diffuses through membranes such as those around cells (called semipermeable membranes because they are nearly impermeable to ions but very permeable to water), this diffusion of water is called osmosis. Osmosis is the reason that the skin on our hands wrinkles into "prune fingers" when we stay too long in the bath or shower. Water diffuses from the higher water concentration (but low salt concentration) of the fresh water in the bath into the lower water concentration (but higher salt concentration) of our skin, causing it to swell and be thrown into wrinkles. The exact opposite happens when we immerse ourselves in sea water at the beach and our skin, particularly on our hands and faces, shrinks by osmosis and feels tight."

What kind of receiver? A small "scanner" type receiver, for example, typically overloads if connected to a large antenna, so a short whip works best for much of the range.

And how "good" is "good"? If you use a long antenna at high frequencies, it'll have multiple lobes. So there will be many directions where you won't hear very well. Is that ok for your application? No single antenna will do terribly well over that entire frequency range.

My suggestion is that the person asking the question get a roll of wire (hookup or magnet wire is fine) and experiment, to see what's best, or good enough, for his particular receiver, location, and listening habits.

My old TS-520S is said to put out 160 watts DC CW and
200 watts PEP SSB .
Whats the minimum dummy load requirement to tune it ?

There are kits for 100 watt dummy loads. Would that be
enough for brief (~ 10 sec) tuning ?

Are there standards as to how the rating of a dummy load
is to be interpreted ?

The old tube rigs used power input to finals as their customary metric.
Considerably less power was output as RF power, which is all that the dummy
load is concerned with - assuming that you have a sentient dummy load. 8>)

A standard 200 watt air cooled dummy load will suffice.

Hi Dave,

DC? (Yes, I know, straight from the specification sheet, but
nonetheless: DC?)

>Whats the minimum dummy load requirement to tune it ?

Add 50% for safety factor. Or simply ask yourself, do you need to
tune up with full power? Kenwood is usually engineered well enough
not to demand this.

>There are kits for 100 watt dummy loads. Would that be
>enough for brief (~ 10 sec) tuning ?

Sure. Better question to ask is "can I trust the claims of this kit?"

>Are there standards as to how the rating of a dummy load
>is to be interpreted ?

Something short of:
1. throwing the solder of the connections (a temperature under the
eutectic point if 61/39 tin/lead).
2. ignition;
3. personal harm.

The dummy load's rating can be extended through cooling by forced air
or immersion - so its environment is as much a part of the
specification as anything (it doesn't work as well inside a stove as
it does a refrigerator).

If you are building your own (implied by your reference to a kit);
then it behooves you to maintain the lowest heat path resistance
between the load (the resistor) and the coolant. This generally means
a very tight gas-free bond between the load (the resistor) and the
heat sink and the absence of insulating air on the heat sink surface
(either in the form of an air pocket, poor circulation, or a bubble).

Last of all, how sure are you that the load is actually the Ohmic
value you need? The harder you push it, the less likely it will be
that value. In that case, derating to 25% to 50% is called for.
Frequency can be an issue too.

Caddock's MP9100 50 Ohm resistors are a useful jumping off point for building your own load.

==========

Professional dummy loads are normally rated for continuous use .
They often have cooling fins with the actual resistor being of the thin film type on a heat sinking tab.

I have made my own dummy loads (for HF and lower VHF) from 20 pcs 1KOhm 2watts ,resistor ,so good for 40Watts as is ,but when immersed in motor oil capable of handling 100+Watts for 10-15 minutes.
I used carbon film resistors ,but metal oxide ones are perhaps better.
The advantage of using many resistors (in parallel) is a very low inductance.
I fitted the resistors (sandwiched between 2 jam jar lids with leads just long enough to solder to lids through holes) inside a cylindrical metal can with a SO239 connector fitted in centre of its lid.
To prevent oil 'swetting' from can I covered the seams with solder on the inside. Even after many years ,resistance was 50.6 Ohms or about.
A simple but effective homebrew project.

The numbers you have are the input to the final tubes. The rig will put out around 100 to 120 watts CW.

Dummy loads are usually rated for so much power for so long of a time. Some will be good for 100 watts continious and maybe 300 or 500 for a short time such as 30 seconds , with a cooling off period of 5 minuits.

I have a comercial one that is built with a pl259 on the end. The dummy load is about 3 inches long and 2 inches in diameter. It is rated for 15 watts continious and 100 watts for 15 seconds with a cooling off period of so long. I have ran a 100 watt rig into it for a short period of time. It does get very hot after a few seconds. The old Heathkit dummy I have is a resistor in a gallon 'paint can'. It is full of oil and can take a KW for a short period of time.

I picked up some dummy loads at a hamfest that are good for about 50 watts and not sure how long or how much power they will take. I did hit they with around 100 watts for about 30 seconds to check out a rig and they took it,but they did get very warm.

For the ts520 you can use a 100 watt light bulb. I would not recommend it for any rig with transistors for the output, but it is fine for the tube rigs. Just use about a foot of coax to the light bulb. They will radiate a small ammount of power, but not enough to both most stations.
You just tune for maximum brightness. If you have a wattmeter, it will probably not be accurate into the light bulb as it is not 50 ohms, but good enough to tune the rig to see if the power out is around 100 watts.

If it has a solid, usually plain or tinned copper, shield, it's known as semi-rigid coax. There are no RG numbers associated with it that I know of -- it's simply specified by impedance and outside diameter - 0.085, 0.141, 0.250 inches and smaller are common. Insulation is usually, but not always, solid PTFE Teflon. Various manufacturers offer a number of variations, such as aluminum shield and FEP or foamed dielectric. Each manufacturer has its own part numbering scheme.

UT-141 is often also labelled RG-402, and UT-085 is often also labelled RG-405. Some manufacturers seem to think that there is some level of equivalence.

I added RG-402 and RG-405 to my line loss calculator to cover the apparently equivalent Uniform Tubes types (ie UT-nnn).

Hey, what comes around, goes around ...

Since all your responses to any of my posts have/has been
non-nonsensical, moronic, stupid, ignorant, without substance, vicious,
vindictive, etc., all I can do is repay the favor(s.)

Look for as much worth in my responses to your posts as I have found in
yours ... what? You expected different? LOL!

Good luck, may the others be stupid enough to remain your pawns ...

Regards,
JS

I ran across this 'question' on a forum. The general consensus appears to be the same in both places. Typically, bigger is better, to some ridiculous point. Higher is also better to some ridiculous point. Just depends on what you have available for the antenna and placing the antenna, and what it'll be connected to. And, there's no simple, cheap, small antenna that does -everything- well from day-light to dark. My main purpose was any rules-of-thumb (ROT, I like that one!) that apply to antennas in general. Depending on just how 'general' you want to be, I think it's been covered.

Just to be a little note... some SWLers run a wire from the chassis of a radio to "any" ground realizing a increase in signal. This may be do to the fact that this ground actually becomes part of the antenna so-to-speak. Smply running a wire connected to the chassis out the window and in the other direction of your antenna may do the same thing. However, a safety ground with anything having an external antenna is generally a good idea. :-)

When using a power outlet as a ground, you may incur more noise depending on what equipment is also sharing the same ground.

Yeah, some years ago I read Wheeler's 1947 paper on the fundamental limits there (although one of my old professors, James McLean, was fond of mentioning how many peoples' interpretation of that paper wasn't quite right... and he wrote his own take on it back in 1996). In my case, I intend to use the usual folding techniques to obtain significantly greater overall length than what I'm allowed in any one dimension. When I look at such "meander line" antennas, though, it's often not clear to me if the designer took coupling between the folds into account or not, or instead just used some rules of thumbs to avoid "significant" coupling and then empirically trimmed the antenna to get the input impedance they were after.

> The book I'd go to for researching the possibilities would be Lo & Lee's

Four volumes... wow!

> You might also get some ideas from Bailey, _TV and Other Receiving
> Antennas_, since TV antennas have to be pretty broadband.

That I have a copy of... I think I got it a few years ago when the topic of how "rabbit ear" TV antennas actually "work" was being discussed. (These days I think of them as similar to a tapered slot antenna, which is wideband.)

Thanks,
---Joel

1181. Ham or CB Antenna?

Interesting paper on how the fundamental limits on the Q of antennas applies to real-world devices: www.centurion.com/home/pdf/wp_dimension_limits.pdf -- some antennas perform better than one might initially predict based on coupling to adjacent ground planes (etc.) that effectively make the antenna electrically larger than initially intended!

>"one element short of a full antenna!"

Brett, I see you got the relay, even from someone with one element
short. (Curious sort of thanks you offer your assistant.) At least
it has a asymptotic trajectory towards the topic. Let's just nudge
that into more than a glancing contact:

I know its a challenge for you to stay technical, but how much signal
is lost with that one missing element? Let's say an NBS Yagi. Can
you choose any one element and describe the net shift in dBi? You
couldn't respond to the Subject Line of how a Blackberry could source
5KW to provide -10dBW at 15 wavelengths, so this may be out of your
league too. ;-(

So, for the comic relief we can all count on Brett for, can you,
perhaps, tell us how many missing elements you would have to have to
reduce this pocketed Blackberry's boiling contribution to the sea
water in your Bulbo-Cavernous Artery by one degree Celsius? Please
post your bench test on youtube.

Better yet, don't remove ANY elements and repeat the bench test, and I
bet 60 Minutes will air that! What a coupe! Validation at last! And
I bet they will, probably, maintain your anonymity - maybe (so much
for validation). Anyway, its worth our fun to watch this by any name,
and OK so it will probably only be carried by Mythbusters (poetic
about that too).

So, the NBS Yagi report? The 15 wavelength explanation? Boiling sea
water experiment?

In that the antenna/beam is vertical it is most likely a CB beam
antenna. An amateur radio antenna would be horizontal.

1187. QST antenna article

Newsgroup: rec.radio.amateur.antenna
Date: 2008-08-19 03:53:17 UTC
From: jawod <jawod@fuse.net>
Message-ID: <c0e09$48aa426f$4ad7b981$14125@FUSE.NET>
Source record: 23461

In the latest QST there is an article on a Window line twin lead antenna that uses relays to switch sections in and out of a dipole configuration to allow multiband use. (DC is inserted into the coax to activate the relays.)

Sounds interesting to me.

But...the twin lead is connected directly to coax with no balun. Isn't this a mismatch? I wonder about significant RF coupling to the adjacent dipole sections through the relay assemblies. Also, I couldn't tell if the window line was shorted into a loop at the ends or not.

Any comments?

Thanks

John

The impedance of the dipole is in the 200 to 600 ohm range. The
transmission line is a fair match for the antenna element. A transmatch
is required at the transmitter end though.

It's not a folded dipole. Both wires are fed in phase, and the second wire
is needed for a DC return only.

A belated response to my initial post. After reading all the responses, and after much thought, I have decided to fore-go using a vertical at present.

I have problems with high winds, corrosion, some noise, ability to place an adequate grounds system, and even aesthetics, etc. so I have decided, for the time being, anyway, to put up a rather low dipole (NVIS) instead.

My thanks to all who took their time to give me their opinions and ideas. Its a good learning experiece, even if I don't proceed with the initial plan.

Ed

I have operated 10M FM in the past... using ground planes and vertical dipoles. It is possible that that is a devoted 10M FM ham. However, I'll admit, not likely, and is probably a CB amtemma.

Without some reference for size, anything would only be a guess.
The most common guess would be either a 10 or 11 meter antenna, since
it appears to at least be in that range, sort of. After that, it's
only a guess.

> - 'Doc

The purpose of a balun is to balance the feedline, that is, cause the currents in the two conductors to be equal and opposite so it doesn't radiate or receive signals. Either twinlead or coax can be either unbalanced or balanced. If the feedline is unbalanced, as you say, a balun will prevent the line from radiating or receiving signals.

Anyone interested in learning more about this topic can find more information at http://eznec.com/Amateur/Articles/Baluns.pdf.

How many people have developed the brain tumors associated with cellphone use versus the number of people whose lives have been saved because of the use of a cellphone?

Think of all of the 911 calls that have saved folks' lives over the years that the cellphone has been available to the public.

I am NOT saying that cellphone use is entirely safe. I truly do not know, one way or the other, but, if immediate tumors or other cancers had been developed during the all to brief preliminary testing of devices operating at such high frequencies in close approximation to the human body, I feel certain that said developers would not have rushed their devices into mass production so quickly.

Risk versus benefit must be taken into consideration too.

The ladder-line is NOT used as RF transmission line.
It is used for DC current and for RF antenna current.
This is just an ordinary coax-fed dipole with an extra
wire to carry the DC. There is no BALanced to UNbalanced
RF junction to worry about.

I seriously doubt that the antenna knows the difference. 8>)

I can't see the image very well, but it looks like (to me) that there are two larger and two smaller elements on the mast. As I said, the image isn't very clear, so I could be mistaken.

Problem is, I can't think of a dual band antenna that would use that much spacing between the two interior smaller elements. But what do I know?

It has been an interesting thread. For some reason it never occurred
to me that the tubing sold for chain link fence top rails would make
an inexpensive and durable vertical. TV masting sems to be getting
more expensive and harder to find. I will likely use it for the next
refresh cycle on my vertical.

Of your stated objections only the matter of the ground seems to be
really tough to solve for me. I bet that in time you will try both.
The NVIS and vertical will give you two different sets of contacts!

I don't know what youthink you are doing, but it's not going IMHO to end well. If you think that the resident of the property is operating illegally, on whatever band you think they may be doing so, contact a local ham radio club, or if you don't know of one, the ARRL or local equivalent and ask for assitance in tracking down the source of the interference.

I'm sure there is someone near you who has the skill and the equipment to find out what the problem is and locate the actual source.

Usually they guy with the most visible antennas is the one who is the least likely source of whatever interference you are experiencing assuming you are experiencing some sort of interference and are not just out the get the guy because you don't want anyone with antennas in your neighborhood.

Geoff.

QST antenna designs would be easier to understand if QST used the
traditional electrical diagrams for antennas, instead of those goofball
drawings that have insulators/guy wires/etc. shown as major features. This
particular antenna design, unlike some of the other antenna articles, can be
waded through by looking at the drawing.

What the hell, public forum or not, I need some help here, and this
guy is giving legal users a bad name.

I've approached the guy *several* times over the past few yrs and
asked him very nicely to lower the boost/gain (whatever it's called)
on his radio and he has complaied to a certain extent.

His broadcast were only coming through my stereo speakers during low
passages at the time.

As of a few months ago, it is now so bad, that his broadcast are now
coming through my TV speakers, and causing horizontal lines in the
picture. (on all four of my TV's) And it's so bad on my computer
speakers now, that I have to turn them off. As far as listening to my
stereo, I can't even do that now if he is broadcasting.

So I approached him again, only this time, he told me to "F off", that
"he wasn't doing anything illegal".

When I got home, not only was the broadcast even louder, he was
telling one of his radio buddies about the "incident" in FULL detail.

So, I know for a FACT it is him.

I know just need to know what kind of radio he is using.

Question, can a CB transmit

But actually, that's not the principle.. The actual limits have to do with the ratio of stored energy vs radiated power in the antenna (Q, in the energy storage sense, not in the "resonant circuit" sense). For example, a lot of the efficiency issues in practical antenna systems are more to deal with the reactive component of the feedpoint impedance, and the reactive/lossy network used to make it look like the feedline or transmitter output impedance.

And the classical formulation also makes some not necessarily always valid assumptions: linearity and reciprocity of components being the notable one (Foster vs non-Foster terminations, for instance).

wrote:

>Question, can a CB transmit 700 miles?

At the power levels you are suggesting, globally during certain
periods of the sun spot cycle. But that is not terribly different
with legal CB power.

As to his remarking that he wasn't doing anything illegal (CB with
amplification that some smarmy posters here think is perfectly OK); if
that be the case, then you need to fix your problem, because the FCC
does not mandate that a Ham legally using his equipment is obligated
to defer to your TV watching habits.

That fix is going to be the same if power levels don't go down for any
reason (issues of morality notwithstanding). The judicious and
liberal application of Ferrite RFI suppressors will solve a lot of
your suffering.

Look at any of your computer display leads and notice the end of the
cable with the odd bulge before one connector. That is a suppressor.
It is nothing more than a ferrite donut or tube. Ferrite is a
magnetic ceramic (it will break like china if you drop it). It is
made in many forms and appears to be dark gray with a slick to dusty
finish. The Ferrite RFI suppressors available at Radio Shack come
with a plastic clamshell holding one of these tubes that is split
lengthwise so you can open it, insert a wire or wires, and then lock
it shut. This makes it reusable if the problem isn't solved with your
choice of wire(s) or where you apply it.

This last suggests experimentation on your part is necessary. It also
means you are going to need more than one given you have described a
number of issues. For a start, get two or three and see how well they
work on the power cords going to the affected component (TV, radio,
computer) and even with both wires of any speaker. In short, put a
suppressor on any interconnecting cable or wire and see if symptoms
change.

It is not a folded dipole.

The two sides of the ladder line are connected together at RF at the
input by capacitors C4 and C5 in the splitter making it look like a
slightly fat, ordinary dipole.

If you want to know about RF coupling on the adjacent elements, you
could model it with the demo version of EZNEC.

He's obviously not legal. He has been getting louder and louder over
the years to the point of what I described in my earlier post about
the problem with the TV's now.

And even the very first time I approached him, I mentioned that I knew
he was broadcasting illegally, and that we all have our hobbies, but
his was interfering with mine, which at the time was home theater. He
didn't deny that he wasn't illegal, at the time, and he did lower the
power, for a while.

I've approached this guy at least 5 times in the past few yrs, and
every time he has lowered the power, for a while. Not this time,
though, and it is now out of control.

You are probably not going to agree with this Des, but the fact that you have a problem with your TV and hifi is no indication that the guy with the transmitter is at fault. Hams are legally allowed to transmit with very high power and the fact that your equipment is susceptible to these transmissions is more an indication of your equipment's short comings than the transmitter's. Unfortunately some manufacturers take few precautions to prevent this kind of interference getting into audio equipment etc. They prefer to save money and only deal with complaints when they occur; it is more cost effective for them!! The selling price is no indication of how well a TV or hifi will stand up when exposed to strong transmissions.

Home theatre set ups are especially susceptible due to all the long speaker cables lying about acting as antennas.

Regards
Jeff

Hi Jim,

Different meanings of Q? The measure of Q may vary according to
arbitrary usage: the choice of SWR limits to define bandwidth which
infers Q. Some choose 2:1, classic Q would go further. Either way,
and for either quantitative result, the meaning of Q remains
essentially the same.

That isn't Q, that is matching considerations. Certainly there is a Q
for the system and Q can be extremely high in detriment to getting
transmitting power out of the antenna. This is, albeit, a largely
unattainable situation, but try sending voice communications through a
very efficient 1M loop at 160M.

> guy is giving legal users a bad name.

You have not in any way proved that he is NOT a legal user.

What I've gotten out of your posts are:

1. He is having conversations using a radio.

2. Your stereo system picks them up.

3. You are annoyed by this.

Anything else is in the end irrelevant.

Since he is speaking to someone else, he is NOT broadcasting and may very
well be operating legally. Since you have not said where you are, people
have assumed that you are in the U.S. If that is not the case, this
is the time to say where you are.

> I've approached the guy *several* times over the past few yrs and
> asked him very nicely to lower the boost/gain (whatever it's called)
> on his radio and he has complaied to a certain extent.

That's very nice of him. If he is operating legally, then there is NOTHING
that he MUST do, and he was trying to accomodate you. You were acting
like a neighbor who calls the fire department everytime someone lights
their barbeque.

> His broadcast were only coming through my stereo speakers during low
> passages at the time.

How were they doing that? Do they come through with the stereo off? If they
do it's a problem with the speakers and their wiring. If they don't,
it's a problem with the stereo itself, YOUR antenna, or YOUR power wiring.

> As of a few months ago, it is now so bad, that his broadcast are now
> coming through my TV speakers, and causing horizontal lines in the

Now we are getting somewhere. Are they connected to cable TV? Do you have
an external antenna?

> So I approached him again, only this time, he told me to "F off", that
> "he wasn't doing anything illegal".

I don't agree with the method, but the message is correct. If he is
not doing anything illegal, it's your problem, not his. He's tried to
make a reasonable accomodation (reducing power), but you've done nothing
except complain more.

> When I got home, not only was the broadcast even louder, he was
> telling one of his radio buddies about the "incident" in FULL detail.
>
> So, I know for a FACT it is him.
>
> I know just need to know what kind of radio he is using.

Most likely he is using a ham transmiter in the AM mode. These are quite
rare nowadays, but are perfectly legal. If he were using FM mode it
would sound like a loud continuous buzz, and if it were single side band,
the more popular mode, it would sound like donald duck and you probably
could not understand him.

If he were using morse code, it would sound like buzzing that stops and
starts quickly.

He may be using a CB as many of them are AM, but generally they have a range
of about 5-10 miles. Even with illegal power, due to global cooling (lack
of sunspots), they won't reach far beyond line of sight for another 3-5
years.

At this point if I were you, I would go knock on his door, appologize for
the misunderstanding in the past and ask for him to either give you advice
on what to do to resolve the problem or recommend someone to ask.

My guess is as a start that YOU have an electrician come out and check
the GROUND wire on your electrical system. Make sure YOUR main panel is
in fact grounded and all the outlets you have are really grounded.

Unless you have ISO-BAR (or better) surge protectors, throw them away.
It's not a waste of good money, they are worthless trash anyway.

After that unplug the antenna connections from all of your TV's and
stereo system. Have him transmit a test signal. If they come through the
TV's, or stereo, get power line filters. If no signal comes through the
TV or stereo, and it starts when you reconnect the antenna, get a better
antenna (shielded wire) connection with a proper ground and a "high pass"
filter.

Get good computer speakers anyway. Try USB ones instead of ones that
plug into your sound card.

There is nothing to distinguish a Ham from a CBer here.

>He's obviously not legal.

As you came here to make a determination of class of operation, your
statement is clearly a guess, not "obviously" a correct observation.

Simple point in fact is that even for a professional, it is
exceedingly difficult to determine a power level that is not legal.
You, as a citizen, are perfectly empowered to notify the nearest FCC
field office that is equipped to do this, but I wouldn't hold my
breath. Your tax rebate check robbed that agency of enforcement power
funds so you could buy a new TV. You can change that at the ballot
box - expect a higher tax bill if you want government to solve this.

Yes, not pleasant at all. Your complaint is neither new, nor original
over the course of 80 years now. In all practicality, your only real
option is to go to Radio Shack and stock up on suppressors. Save
yourself the added postage cost of sending a letter to the FCC and the
delay of bureaucracy waiting for them to tell you the same thing.

Make that "transmission line junction". Of course, the
UNbalanced coax to BALanced dipole connection could use
a 1:1 choke.

How do you know that? It could very easily be that YOUR problem is getting worse. You just automaticly blame him without doing anything to determine what the real problem is.

I'm probably at least 6,000 miles away from you but you should check out what I wrote in my last post very carefully. I think in the end not only will you owe him an apology, but you will thank him for pointing out a situation which could cause your house to burn down with you in it.

BTW, do you happen to live in Willingboro New Jersey? Or somewhere built around the same time? *

Geoff.

* Aluminum house wiring, which if you do have it, it ALL should be replaced. Aluminum wiring from the pole to your main panel is ok, but in the walls, it's a disaster working up to the "big one".

Thank you, very much!

Since I didn't know his name, I just started clicking on all of the
names in my zip code, and his address popped up.

So, it is definitely a Ham.

Thanks for everyone's advice and help!

The health risk from an unshielded CRT would be significant. I'm not so
sure about the risks from cell phone near field RF (yes, I know the
discussion is often far field, but sometimes I think I'm "wrong" because
some people don't like John Smith.

At the risk of bringing actual research into this

http://tinyurl.com/6ghw69

It is a pdf with abstract/conclusions of several studies.

A lot of interesting stuff there. I haven't read it all yet - its 76
pages long, but at first blush, it appears that it is unlikely to have
carcinogenic effects. Some studies see some things happening, but that

doesn't necessarily lead to a carcinogenic conclusion.

At the same time, there are some EEG effects that are very interesting.

Take a look, and try not to focus on only the effects that say "no problem here!" or "problem here!"

Keeping in mind that many of these tests are very specific (as they should be to build a knowledge base) It is not overwhelmingly difficult to come to the conclusion that there might be something going on that is not carcinogenic, but neurological in nature.

Even in one of the tests, there are people who report a warming feeling on their hands and around the side of their head when using a cell phone for an extended time. I'm one of them. While the hand feeling could easily be attributed to the battery discharge warmth, the feeling around the ears is more difficult to ascribe to the batteries.

> But the bannanas and granite countertop in the kitchen might be a problem.

There are some granite counter tops that are significantly radioactive. What surprises me is that the fact surprises so many people.

So anyhow, the research is submitted for bathroom reading, People can feel free to discount/invalidate whatever research they don't agree with......

>though, and it is now out of control.

Well, I have some good news and some bad news for you.

Let's do the bad news first, OK?

As others have pointed out, it's entirely possible that your neighbor is transmitting legally. If he has a ham license, he could be transmitting with power levels of up to 1500 watts, in most bands, and still be entirely within the bounds of his license.

The fact that he "didn't deny" that he was "broadcasting illegally" isn't proof, by any means. He may simply have not wanted to get into an argument with a neighbor who was making harsh accusations without proof or evidence (and, sorry to say, I *am* referring to you here).

Unless you have evidence that he's transmitting without a license, or in ways which violate whatever license he has, you don't have much legal leverage, and probably won't be able to persuade anybody to do anything on your behalf.

As others have pointed out... if a stereo amplifier, or loudspeaker, or telephone starts picking up and reproducing radio transmissions, then *this* device is defective/broken/badly-designed. This is a condition referred to as "undesired operation" - the phone or speaker is reacting to something (a strong RF field) which is irrelevant to this device's normal mode of operation.

It is the position of the FCC that such "undesired operation" is a defect in the device in question, and not the fault of a (legal) radio transmission. It's is technically possible (and not all that difficult) to shield and filter devices such as amplifiers and phones so that they don't react to RF fields. Some manufacturers skimp on this filtering and shielding, in order to save money... and if the

consumer buys such a device (rather than a more expensive, better-designed one) then any problems which result are the responsibility of the consumer and the device's manufacturer.

Many, many consumer electronics devices these days come with a "Part 15" label or advisory, on the device or in the manual. Part of the wording says these devices "must not interfere" with licensed radio services, and "must accept" interference from both licensed and unlicensed radio services "including interference which causes undesired operation".

That's the bad news.

Now, for the good news.

It's usually possible to add some after-market RF suppression devices to the affected components, and greatly reduce or entirely eliminate the interference. You can buy such devices over the counter or by mail, and they're not expensive.

For phones, a small filter which plugs in between the phone cord and the wall outlet will often do the trick. Plug-in DSL filters are commonly available and will probably do the job well enough.

For loudspeakers and stereos - in most cases I've seen, the RF is being picked up by the wires between the speaker and amplifier or PC... the wires act as antennas, carry the RF into the amplifier section, and the amplifier "detects" the RF by accident and converts it to audio and amplifies it. It is often possible to entirely eliminate such unwanted pickup by adding an interference suppressor (a.k.a "choke" or "ferrite") to each speaker wire, right before it enters the amplifier. The commonest variety is a "snap-on" two-part ferrite - snap it open, wind the speaker wire through it a few times (leaving a short stub of wire at the end), snap it closed, and reconnect the wire to the amplifier/receiver. With amplified speakers (computer or subwoofer), put a ferrite right at the speaker end of the wire.

Adding ferrites to the AC power cords of the receiver, amplified subwoofers, etc. is also a good idea.

For TV interference, you may need a "high-pass filter" connected in the antenna line right at the TV. This will keep the strong RF signal from your neighbor's transmitter out of the TV set's receiver.

Ferrites and filters are probably available at your local Radio Shack, or by mailorder from quite a few suppliers.

For further information about actually solving the problem, I'd suggest that you look at the ARRL's extensive collection of information about this issue. Start at

http://www.arrl.org/tis/info/rfigen.html

for a table of contents and a good overview of the basic issues involved. The "Information for neighbors of hams" page is also worthwhile reading.

Oh... if you want to know whether your neighbor is a ham, you may be able to find out from:

http://wireless2.fcc.gov/UlsApp/UlsSearch/searchLicense.jsp

Click "Amateur", then plug in your zipcode and do a search. See if your neighbor's name comes up.

However, even if your neighbor doesn't have a ham license, and is transmitting on CB, it's entirely possible that his transmissions could be getting into your radio even if they were limited to legal power... and if so, he wouldn't be under any obligation to stop transmitting or reduce power.

In my limited experience it is not the power level that leads to the
interference but excessive modulation level. Over modulation leads to
spatter all over and is lost power as far as the user is concerned.

In other words, he would put out a larger signal if he kept it to the
intended frequency. Unfortunately those who flaunt the law are seldom
interested in facts.

If it is infact a legal transmission you should at some time hear
callsign information.

> essentially the same.

Actually, the Q you use is not the actual definition, which is the ratio of the energy stored in the system vs the energy lost per cycle (or possibly per radian, so there's factor of 2pi in there)

The articles that talk about size, efficiency, and Q, use this definition (Energy stored in near field vs energy radiated away). (e.g. the papers by Chu, Harrington, etc.)

For a single LCR tuned circuit with reasonably high Q, it just happens that the BW/CF works out to the same thing (because it's a quadratic equation that determines both..)

Chu, 1948, defines Q = 2*omega*mean electric energy stored beyond input terminals/(power dissipated in radiation) (page 1170). he goes on to say,"We have computed the Q of an antenna from the energy stored in the equivalent circuit and the power radiated, and *interpreted it freely* as the reciprocal of the fractional bandwidth." (my emphasis added) " To be more accurate, one must define the bandwidth in terms of allowable impedance variation or the tolerable reflection coefficient over the band. For a given antenna, the bandwidth can be increased by choosing a proper matching network. The theoretical aspect of this problem has been dealt with by R.M. Fano."

Harrington, 1965, considering directional antennas (Chu dealt with omnis) defines Q as = 2*omega*W/Pin [eq 54], which is slightly different than Chu. W is either We or Wm (the energy stored in the E or H field respectively), and Pin is the input power to the array. He goes on to say,"If the Q is large, it is related to the frequency bandwidth of the

array as follows. Consider the array to be resonated by a suitable reactance network at the frequency of interest, omega/sub/r. Define the ferquency bandwidth of the array in the usual manner to be the fractional frequency increment between the 0.707 points on the normalized input |Z|,
beta = deltaOmega/Omega/sub/r. [eq 56]

If the Q is high (say Q>10) then we have the relationship:
Q approx= 1/beta [eq 57]"

Note well the "approximately equal" and the "resonated by a suitable reactance network"

SWR bandwidth is something totally different of course..

But again, if you pick the right SWR value for your bandwidth measurement, then a dipole antenna is modeled pretty well by a single pole LCR resonant, so the math works out conveniently the same.

Once you start straying away from antennas that can be modeled as a single LCR, the "bandwidth" vs "Q" relationship goes away.

A good example would be some forms of phased arrays with non-reciprocal devices. Antennas with multiple resonances would be another case (except if you are only working over a restricted range, where the single resonance in your range is approximated well by a single LCR)

I agree with you, Dave, but it's the usual case where it sure *looks*
suspicious if someone who's doing something entirely legal doesn't claim as
much when accused of doing something illegal. Something like, "Actually, I'm
a licensed amateur radio operator, and my setup is perfectly legal, although I
don't really care to debate this with you -- good day." is in no way
provocative.

I would suggest that the O.P. contact his local amateur radio club and see if
anyone there has a spectrum analyzer -- that should very quickly resolve the
question of whether he's transmitting on 11m or some ham frequency. If it is
a ham frequency, I would agree that realistically one has to assume he's
transmitting well within his legal rights, as (1) exact power measurements
aren't going to be easy and (2) perfectly legal power levels can still cause
plenty of interference.

I would hope that all hams would be intersted in assisting the O.P. in this
case. While the transmitter may well be a hermit ham operating perfectly
legally, it's certainly in the amateur community's interest (and perhaps even
charter) to help the O.P. out by at least verifying that the transmissions are
plausibly legal, and then providing suggestions on reducing interference (if
they are legal), as you have done.

> However, even if your neighbor doesn't have a ham license, and is
> transmitting on CB, it's entirely possible that his transmissions
> could be getting into your radio even if they were limited to legal
> power...

Also true, but highly unlikely, IMO. This can usually be verified by just
listening to the guy for awhile -- pretty much every CB'er I've ever met who
had an amplifier liked to brag about it at some point on the air.
Additionally, if some local ham with a spectrum analyzer can additionally
estimate the gain of the antenna, he can estimate what sort of signal power a
5W CB should produce with a test dipole connected to his analyzer. If he's
getting, e.g., 20dB or more above the estimate, the likelihood that it's a
legal CB transmission is effectively zero.

Umm... many cell phones get noticeably warm over time due to internal power dissipation. (In fact, the amount of heat generated by the battery is negligible compared to the heat generator by, e.g., the RF power amplifiers, the digital circuitry, etc.)

How many studies have been done looking for beneficial health outcomes from the use of cell phones? Like wine and alcohol in moderation are now considered to be!

What the hell, public forum or not, I need some help here, and this
guy is giving legal users a bad name.

I've approached the guy *several* times over the past few yrs and
asked him very nicely to lower the boost/gain (whatever it's called)
on his radio and he has complaied to a certain extent.

His broadcast were only coming through my stereo speakers during low
passages at the time.

As of a few months ago, it is now so bad, that his broadcast are now
coming through my TV speakers, and causing horizontal lines in the
picture. (on all four of my TV's) And it's so bad on my computer
speakers now, that I have to turn them off. As far as listening to my
stereo, I can't even do that now if he is broadcasting.

So I approached him again, only this time, he told me to "F off", that
"he wasn't doing anything illegal".

When I got home, not only was the broadcast even louder, he was
telling one of his radio buddies about the "incident" in FULL detail.

So, I know for a FACT it is him.

I know just need to know what kind of radio he is using.

Question, can a CB transmit

Yes, CB radios transmit. They wouldn't be of much use if they didn't.

It is possible that your neighbor IS doing everything legally and that your particular situation is what is causing the reception of unwanted radio waves.

Go to Radio Shack and ask them if they have any devices that will help block out your neighbor's transmissions. I know that they used to sell such devices. I don't know if they still do today. If they do not, you can look for sellers on the internet.

Years ago, Congress was presented with a bill that would have required all consumer electronics that were susceptible to RF interference to have factory installed devices that would eliminate the problem. The estimated additional cost per each consumer electronics device was $1.50. The electronics industry lobbyists convinced the congress critters that it would be too expensive for them to do. So, congress voted down the bill. If you're really pissed about your situation, jump up and down on your congress person via TELEPHONE. They don't read their emails. At least they don't yet. They will someday, but the phone is the best way to make your point.

If you are using rabbit ears for TV reception, you don't stand a chance of winning your case with the FCC. If you are utilizing a properly installed TV antenna, the fix is simple. Your computer speakers can be muted by buying aftermarket ferrite cores and installing them on your speaker leads. It is up to YOU to eliminate the RF interference that your appliances are experiencing. Not the radio operator.

Typically, it is up to you to fix your interference problems and not that of the CB or amateur radio operator. Yes, it sucks, but that's the way it is. Whether the CB operator is operating legally or not is between he and the FCC. It bears no relevance to you. Keep pestering the guy and you could end up with a broken nose.

If the offending freq(s) is/are in the CB band (and EVEN if he is running a PA/linear), how about a trap filter to remove them (the freq(s)) and prevent them from overloading the front end of your set(s?)

Hi Jim,

If you will note, my example was a measure, not a definition of Q.
The half power points bandwidth compared to the center frequency is a
classic computation of Q. As I point out, the choice of 2:1 SWR, not
being half power points, is arbitrary but in no way diverges from the
sense of Q (and could be extrapolated anyway).

>The articles that talk about size, efficiency, and Q, use this
>definition (Energy stored in near field vs energy radiated away).
>(e.g. the papers by Chu, Harrington, etc.)

Use "which" definition? You offer what appear to be two, and that is
one too many.

>For a single LCR tuned circuit with reasonably high Q, it just happens

> beta = deltaOmega/Omega/sub/r. [eq 56]
>
> If the Q is high (say Q>10) then we have the relationship:
>Q approx= 1/beta [eq 57]"

Hence the two definitions? What I see are computational models for
different systems which arbitrarily restrain loss to inhabit their
model or exclude it. Q can deteriorate considerable if you open the
definition to include more components going back to the power supplies
to the finals.

>Note well the "approximately equal" and the "resonated by a suitable

This example needs a sub-example: Non-reciprocal devices? I don't see
how this will alter the concept of Q.

>Antennas with multiple resonances would be another case
>(except if you are only working over a restricted range, where the
>single resonance in your range is approximated well by a single LCR)

All antennas have multiple resonances and it is a classic
differentiator between themselves and LCR circuits. I see no example
here that is not already offered by my original post.

Let's simply return to the quote I responded to:
On Tue, 19 Aug 2008 09:17:01 -0700, Jim Lux <james.p.lux@jpl.nasa.gov>
wrote:
>(Q, in the energy storage sense, not in the "resonant circuit" sense)
embodies two explicit definitions of Q:
1. Q for energy storage, and
2. Q for "resonant circuit."
The measurement of Q might deviate by the result offered, but
conceptually energy storage and resonance are inextricably congruent.
If by resonance you are suggesting ONLY the peak frequency, then it
follows there is(are) some other frequency(ies) that are not resonant
(a tautology), and Q follows by exactly the same relation and degree
as it does for energy storage.

If there is any suitable distinction of Q in an antenna, then it is
that the degradation of Q is a benefit to the antenna, IFF the
substantial portion of R is radiation resistance. If the benefit of
filtering (phasing) due to resonance were not an issue, then a Q of 1
would be the Holy Grail of antenna design. Even in the design of the
finals stage in a tube amplifier, Terman teaches us that the final's
tank should NOT have an excessive working Q (beyond 10-15); hence a
high Q is NOT beneficial. Q and efficiency are a slippery topic when
you try to tie them together.

>Since I didn't know his name, I just started clicking on >all of the
>names in my zip code, and his address popped up.

>So, it is definitely a Ham.

>Thanks for everyone's advice and help!

He could be a ham , but also operating on the CB at times. If you can hear him comming in with a clear voice on your computer or sterio speakers, he is probably operating AM and not in single side band. If you got his name and call leters off the FCC data base, you should hear him give the call leters atleast once every 10 minuits. If you do not hear them,but he uses one of the made up names, he could be operating out of the ham bands and on the CB with too much power. This is not legal.

As pointed out , many computer speakers and other home items are not resistant to radio transmitters. It is up to you and the maker of the speaker, or other devices to correct this problem. If he is operating with illeagle power or out of the ham bands then it is his problem.

Well, here's another bit of my take on the matter.

By doing what you did, you (implicitly) put all of the blame and responsibility for fixing the problem on his shoulders.

If he is in fact a ham (as your subsequent message seems to indicate), and if he's transmitting legally within the scope of his license, then *anything* he did to help reduce your undesired-reception problem was a *favor* to you. It was not required by law.

In retrospect, you might have gotten better long-term results if you had instead approached him and said,

"Hey, my stereo is picking up your transmissions. Is there any way you can help me eliminate this problem?"

If you had phrased it that way, you might have a long-term solution by now... you'd have indicated that you were open to possible solutions other than "Hey, turn that blasted thing down!"

You didn't... because you didn't realize at the time that in a situation such as this (if it's actually "ham radio transmissions being picked up by consumer-electronics equipment"), the law says that it is *your* responsibility to fix the problem, and not his. Instead, you seem to have just repeated your demand that *he* fix the problem (by changing his behavior).

I agree with others, that your neighbor could and should have done more to help bring matters to a friendly and successful conclusion. He could have educated you as to the actual cause of the problem, and how to go about truly fixing it. He could have been a better "ambassador" for ham radio. It's a shame that he didn't. Possibly he didn't know how to go about doing this well... or possibly he's just a jerk (some hams are, alas).

On the other hand, it's possible that the attitude you were expressing at the time was hostile enough that he wasn't inclined to be a nice guy and go to extra effort to calm you down and explain matters in a helpful fashion.

At this point, the bridges between the two of you *may* have been burned... or, you may be able to rebuild them, and get into a dialog with him which will bring matters to a successful conclusion.

In order to do so, I suspect that you may have to eat a bit of crow... by going to him and say "Hey, guy, I'm sorry I hassled you so hard. I realize now that you're a licensed ham, and I understand that you do have a right to transmit. I'd like to ask you for help in figuring out how to filter my radios and TV so that your transmissions don't get into them so badly."

If you're willing to do that, I think there's a fair chance that you'll get a helpful response.

>His broadcast were only coming through my stereo speakers during low
>passages at the time.
>
>As of a few months ago, it is now so bad, that his broadcast are now
>coming through my TV speakers, and causing horizontal lines in the
>picture. (on all four of my TV's) And it's so bad on my computer
>speakers now, that I have to turn them off. As far as listening to my
>stereo, I can't even do that now if he is broadcasting.

I feel I ought to point out a minor terminology issue here (which is something that your neighbor would know as a ham, but which you weren't aware of).

In FCC language, a "broadcast" is a one-way transmission - somebody sends it, there's no direct response from whomever is listening (if anyone is). TV stations broadcast. Commercial radio stations broadcast.

Hams don't broadcast - with very rare and specific exceptions, we aren't allowed to. We "transmit", in a two-way conversation with one or more other hams.

>So I approached him again, only this time, he told me to "F off", that
>"he wasn't doing anything illegal".
>
>When I got home, not only was the broadcast even louder, he was
>telling one of his radio buddies about the "incident" in FULL detail.
>
>So, I know for a FACT it is him.
>
>I know just need to know what kind of radio he is using.

It's not likely to be easy to tell just by looking at his antenna, because the CB frequencies (the 11-meter band, around 27 MHz) are very close to those used in one of the ham-radio bands (the 10-meter band, around 28 MHz). If he's transmitting CB with enough power to get into your radios, then he's probably breaking the law... but if he's transmitting on 10 meters using his ham privileges, then there's a very good chance that he's entirely legal.

You'll probably need access to a radio receiver or some test equipment
to determine accurately what frequency he is transmitting.

A simple RF frequency counter, hooked to a few feet of wire, would
probably be sensitive enough.

A CB radio, tuned through the channels, would let you determine
whether he's transmitting on a (legal) CB frequency.

A ham-radio receiver, or a general-purpose shortwave receiver which
works up through 30 MHz, would do as well, as long as its dial is
calibrated accurately enough.

>Question, can a CB transmit

Yes, it can. CB radios are limited by law to a relatively low power
and to relatively short distances (and, unfortunately, these laws are
broken just about as frequently as the laws against jaywalking).

I agree with another comment that was posted - it's unlikely that a
legal-power CB transmission would cause your problems. Legal CB AM
transmissions are limited to around 3.5 watts of RF power, and in my
experience one usually does not start getting "break-through" into
consumer electronics equipment until the RF power is up in the range
of 20 to 30 watts (depending on frequency, antenna gain, proximity,
phase of moon, and about a dozen other factors).

At this point, my advice is to approach your neighbor in a non-hostile
fashion, and ask him for help in fixing your problem (rather than
demanding that he shut down). As others have pointed out, if he's a
ham and is acting legally, the FCC almost certainly *not* provide you
with any help or ammunition in shutting him down, and your local legal
authorities have no jurisdiction to do so.

If you don't feel comfortable in approaching him in person at this
point, try writing him a friendly letter.

At this point in the sunspot cycle, I would think that to be the case, though summertime sporadic E propagation can put a CB signal down at that distance.

> the problem with the TV's now.

How many times have you changed your equipment over the years? I mean your audio equipment is responding to RADIO signals. Those are not audio signals and the problem really lies in the fact that your equipment is responding to radio signals that it SHOULD reject. As the years have gone by, audio and TV equipment has used smaller and smaller devices. Vacuum tube TV sets were virtually immune to this kind of interference (though not to harmonic interference). Vacuum tube stereos were almost never affected. Transistors began to dhange that. This is because transistors are essentally the same kind of thing early crystal set radios were made from. With the advent of microchips, the problem got excessive, because some of the transistors are much tinier than the crystal-catwhisker junctions of the old crystal sets. So put a strong radio station, especially an AM or SSB station (if you're able to copy your neighbour, that might be a clue that he's using CB, as few hams use AM these days, but if he sounds like Donald Duck and you have to strain

to make him out, he's more likely a ham) near a modern stereo made by companies more than willing to save 10 cents per product by leaving out any credible attempt to suppress radio frequency pickup, and you have the makings of a nasty problem. My Kenwood stereo is remarkably immune, but Kenwood also makes and sells amateur radio equipment and has a reputation to uphold with the users of same. Even so, I needed suppression on the line cord, the stereo input cabling (except the digital inputs) and all the speaker leads.

If he is running on the CB band. a local ham should be able to at least veryify this. Power on CB is limited to 5 watts AM carrier or 12 watts peak SSB power. Hams, on the other hand, are permitted a kilowatt.

> I've approached this guy at least 5 times in the past few yrs, and

Knowing the dimensions of the antenna might help, along with a better picture.

> <snipped> helpful info
>

One more thing, if he's a ham, he will sign his callsign fairly often, whereas CBer's don't really have them anymore.

Cable. And the house was completely rewired inside and out about 4
yrs ago.

Just had the cable company out here last week, and they said there was
nothing they could do because everything was in working order.

While there are exceptions to the rule, generally cable installers are not
electronics savvy. Installing cable does not require any education in
electronics. That is why most cable companies subcontract their installation
work to independent folks. They don't want to have to pay qualified
electronics people at positions other than the head end.

So, don't think that the cable guys have the final word on your situation.
Being a home theater enthusiast, it will be good for your system's
performance for you to become proactive and learn some electronics. No one
will care for your system as well as you will.

Simply in an effort to provide a bit more insight, or perhaps I should better say to suggest a math tool that may lead you to more insight, consider what "mutual impedance" means. In a simple circuit where there's a current through an impedance, the voltage drop across it is given by V = Z * I. If you expand this idea to include mutual impedances, the Z becomes a matrix, and I and V are vectors. So in an antenna system with, say, four feedpoints, V becomes a vector of four voltages, one for each feedpoint, and I similarly is a vector of four currents, one for each feedpoint. Z is then a four-by-four matrix with self-impedances along the diagonal and mutual impedances off the diagonal. It is clear that if you know the four currents, you can find the voltages. Further, if you can invert the Z matrix, then you can calculate the currents if you know the voltages. That also suggests how to find the mutual impedances: if you excite one feedpoint with a known current and leave all the rest open, you can measure the voltages at each (including phase) and that immediately gives you the mutual impedance from the excited feedpoint to each of the others: your I vector has only one non-zero component. Repeat for each feedpoint.

You can use the same sort of analysis with other systems which have interaction among components. For example, a system of inductors which share magnetic fields can easily be characterized by a matrix of self-inductances and mutual inductances. For a single inductor, V = L*di/dt; if you have two coupled inductors, V1 = L1 * di1/dt + M12 * di2/dt, and V2 = M21 * di1/dt + L2 * di2/dt -- or in matrix notation, V = L * d/dt(I). That can expand to as many inductors as you care to consider.

(If this is confusing, it's probably best to just ignore this suggestion...)

Cheers,
Tom

Not at all, thanks for the additional details, Tom.

Somewhere I have copies of IEEE tutorial articles on this sort of generalized circuit theory... they ended up as references for work I did in college. (We spent the bulk of our time worrying about scattering parameter matrices, however. I did write some Matlab code to do n-port conversions between S, Y, and Z parameters, though -- but based off of formulas from papers: I question if I could have correctly derived the conversions between, e.g., S and Y myself in a reasonable period of time, since the port terminations for the scattering parameters were allowed to be arbitrary at each port and the math for this requires a decent background in linear algebra.)

>

I have had interference from neighbors with CB units. I have had RFI
from my own equipment--mostly with my VHF xmitters and old coaxial tank
circuits. In every case of mine, going to a cable company completely
removed all RFI ...

Still, I wonder about a stub trap/filter made out of coax, on a
tee-fitting and the length pruned to rid the offending freq(s.) I have
only done such a thing in the past when I was using twin-lead and was
able to construct a trap for an offending VHF freq out of two ~8 inch
lengths of twin-lead with a variable cap the ends of the
twin-lead/8-inch sections (other two ends of these were shorted to form
series loops with the twin-lead sections.)

I have never had to duplicate the above with coax ... but I am sure
someone here has played with such enough to be an expert ... other than
that, I would have little experience to offer ...

If the signal is coming across the ac power, perhaps a "brute force
filter", but I haven't seen one of those to purchase in ages. The
internet or hams here may have construction details ...

Nice set of bowling balls! <grin>

I stopped short of commenting on the "warming effect" ... yes, even the wife has remarked on it, I am only surprised you are the first, other than me and the wife, which has made comment on it--I had just written it off to warm batteries and paranoia ... could it just be the batteries? I wonder ... but if most are willing to argue the obvious--that question could/would "roll on forever ..."

The Li-Ion battery in my DV9000 HP 17" laptop are away from
processor/hard-drive/video-card (high circuity heat sources), the
battery GETS HOT all on its' own ... my cell phone is also Li-Ion so I
do think most of the heat generated is from the battery--testing to
prove all this one way or another is simply beyond my time allotments
and means to do so ... I will accept that "cell phone heat" is
explainable to battery/components/circuitry and simply is transfered, or
the "sense of heat is transfered", to body components in close proximity
... it certainly is the MAJOR component of this "perceived heat."

>I know just need to know what kind of radio he is using.
>
>Question, can a CB transmit

Yes. A CB can transmit.

Now, about your problem. Here's the deal. Your stereo, your TV and
even your CD players are all FCC Part 15 devices. That means that
they are at fault if they are receiving interference from properly
operated, licensed equipment. Your Good Buddy neighbor, operating CB
or Amateur Radio is operating under FCC rules part 97 and/or 95. As
such, their operation is protected by the Federal Government. What
that all means is this: THE RESPONSIBILITY FOR MITIGATING ANY
INTERFERENCE ISSUES FALLS FIRST ON YOUR SHOULDERS.

Have a nice day...

Did things get better or worse when they did? It's simple to test,
just DISCONNECT the cable from your TV's and stereo and see what happens.
Make sure to unplug any cable boxes you have from the wall, because they
may be picking up the signal and leaking it into the power lines (rare
but not impossible).

No strange voices from them, wiggly pictures, etc, then it's likley a
cable problem.

Cable systems can have bad grounds, poorly installed connectors, improperly
sheilded amplifiers and so on too. As someone else said the cable company's
subcontractors are not always able to tell if anything is wrong with the
instalation or the equipment.

BTW. do you have a cable modem for the Internet? I'm guessing their is
a common thing here, and it's the cable system.

Geoff.

Strange, I could have said just that!. Oh wait, I did. Look, it is easy for a person's hand to get warm and attribute it to battery warmth. I trust you are not ascribing the same for an area that the phone isn't touching? That is easy to check for, as the hand would be heated by conduction, and the area around the ear that isn't being touched would be radiative heat. Other wise there would be a significant thermal gradient.

> How many studies have been done looking for beneficial health outcomes
> from the use of cell phones?

Probably none. The reason why is that the studies are looking for effect in general, not positive or negative ones. To look for a specific positive or negative from the start is more in line with creation science.

> Like wine and alcohol in moderation are
> now considered to be!

It is easy to find out the effects of alcohol. Lots of studies. And they found out a lot of things they didn't expect, such as keeping the blood vessels clean, and other more obvious things such as stress relief/relaxation in moderation.

I'm certain that if some positive result is found, we'll hear about it.

During the daylight hours, trees and other plants do make oxygen. At
night, in the dark, they do consume some of the oxygen--however, there
is a net gain; i.e. they do "make oxygen."

Hi Mike,

Did you read the material you offered yesterday? Science reveals all
results observed without going into a study mining for expectations as
you rightly offer here.

>I'm certain that if some positive result is found, we'll hear about it.

The very first study, on the very first page with the very first
paragraph offers:
"Overall,the TDMA field-exposed animals exhibited
trends toward a reduced incidence of spontaneous
CNS tumors (P < 0. 16, two-tailed) and ENU-induced
CNS tumors (P < 0.16, two-tailed)."

The very last study, on the very last page with the second paragraph
offers:
"For an effectively transmitted power of 0.25 W,
the maximum averaged SAR values in both cubic
and arbitrary-shaped volumes are, respectively, about
1.72 and 2.55 W kg-1 for 1g and
0.98 and 1.73 W kg-1 for 10 g of tissue."

These choices are offered as they represent what a reasonable, but
only slightly interested reader would peruse while ignoring the bulk
of the document. As no one has shown any interest in the bulk, and
even less in the first page (much less the last); I introduce it here
to everyone's embarrassment. Don't worry, the feeling will pass with
alacrity.

Interpretation is the name of the "game" here in this forum and I am
sure Brett would find plenty to worry about when the first study says
that exposure REDUCES tumors in the Central Nervous System. The Bible
must inform us this is an error and only Satan could have published
the first study.

The last study gives us more exposure data (the discussion of which inevitably scatters in the rhetorical wind of debate). I can only wonder if the reader can draw a conclusion from this quoted sentence that can be expressed in temperature rise. There's enough data to do this, only intelligence remains to perform.

Your link, like the data of the original post, offers enough data to warrant informed discussion. The original post's data reveals a howler of invention. That cast aside, it allowed a cascade of spiritualism to dominate. Let me kick off the next side-thread of belly-button contemplation and ask: "Why don't we see this data discussed?"

Since you seem more than willing to act as an expert and inform the masses that a 300mw, omni-directional, source of cooking band freqs held millimeters from the skull does absolutely no damage what-so-ever, at just what power intensities should we begin to worry and expect damage? One-watt, ten-watts, one-hundred-watts, one-kilowatt, multi-kilowatts?

Perhaps your point is that human flesh is unaffected by microwave energy which cooks our food and any power level can be tolerated by the body? You will excuse me if I hold out for much more "in depth" studies done by institutions/colleges/consumer-watchdogs, etc. which have absolutely "no horse in the race!" Decades of living with "safe radiation levels" established for atomic elements sources which were "re-evaluated" to downward levels many times has made me a bit more cautious than yourself ...

Perhaps these are the "evolved cell phones?" Produced from throwing handfuls of metal, glass, plastic, etc. into a mud hole, allowing these elements "to evolve" and then digging out the cell phones? Well, of course I would expect different than yourself! I purchased a manufacturers cell phone! ;-)

We're both right, Dave. Trees produce CO2 or O2 depending on the time
of day. I can smell the changeover as it is getting dark and the trees
shift.

Oh yeah, and "Technically", only an "Amateur" one at that ... :-(

Probably only be ethical to emphasize that as well, so your "expert qualifications" are well defined and placed in a proper position in your shoe box ... some of us are only relying on our "logic based opinions" to exercise caution on and defend against money, power, greed, corruption, etc. which may fail in the face of our best interests ...

Not all of it yet. I confess to skimming the oncological studies - although I did notice the tumor reduction outcome. Interesting.

A very good question indeed! I might speculate a bit here.

It is a big complicated world, and so many people are intellectually lazy. It is easier to say "RF exposure is bad" than it is to actually find out if it is. It is easier to say "liberals are the cause of all life's problems" than it is to investigate and find that the last liberal died in 1985.

So many people are capable of great suspension of disbelief. There are people who protest vigorously against a cell phone tower in their neighborhood because of "RF exposure", yet I don't doubt some of them use cell phones. It's just a little thing - it can't be bad....

Look at radioactivity for instance. While people are scared spitless over it, these same folks would put that granite in their houses, sometimes tons of it, and can't even figure out that the granite comes from a volcanic process that is mixing all sorts of minerals, including hot ones.

But they are too busy watching "Beauty and the Geek or some other trash on television. I dunno why, many of these folk are intelligent, yet stupid at the same time.

It is apparently hard to get at the truth.

Let's not forget the propaganda effect. The tobacky industry for years fought off the fact that tobacco is a cause of a whole lot of problems, from cancer to emphasyma and more. Just as there is a whole lot of money involved in both Cell phones and tobacco, there is a lot of reason to discount any problems caused by them.

Now that being said, the "other side" can use those same examples to say that the Cell phone industry equates with the tobacco industry. It does not. Different industries, and just maybe the same tactics.

Sometimes I think it just boils down to some people want them to be harmless, and nothing will convince them otherwise.

Another group wants them to be dangerous, and nothing will convince them otherwise.

A third group wants actual facts, and probably pisses all of the others off..

> touching?

What I'm saying is that a phone uses a certain amount of power -- in the ballpark of a watt -- and much of that is being turned into heat. Although most of the actual heat generation isn't the battery, heat of course flows, so in general the handset can get warm in many places other than where the heat is actually being produced. Batteries tend to get warm because they're good heat sinks, I would imagine.

I agree with you there, although I have a suspicion many studies are desirous of finding deleterious effects.

Hi Mike,

But that is still only the fixated gaze at the belly button. Fully
anticipated and fulfilled. The problem is how to turn off this fire
hydrant.

I would like to see some numbers from data offered - its all there to
give us a temperature rise from KNOWNS! Even Brett's three function
calculator (one function is not approved by creation scienz) might be
able to come close. Unfortunately, for many others it is obviously
more comforting to enjoy gazing upon an approaching asteroid than to
find it is nothing more than a mote in the eye.

There are guidelines available for this from the FCC -- it's a function of exposure time, frequency, and of course power. The numbers have been around for many decades now, and you might recall some questions about it showing up on your license exam.

That being said, I'm not suggesting more studies aren't in order, just that many people have a very mistaken impression that there aren't already many, many studies that have tried to ascertain "safe" exposure levels to RF. (Another thing most people aren't aware of is that cell phone antennas are usually specifically designed to *not* radiate "into" the head. Ham radio antennas usually aren't, yet you see plenty of folking holding up a 5W HT to their mouths...)

> Decades of living with "safe radiation levels" established for atomic
> elements sources which were "re-evaluated" to downward levels many times has
> made me a bit more cautious than yourself ...

Life today is far, far safer overall than it was decades ago. Anything like "safe RF exposure levels" is always going to be a bit subjective, so producing e.g., 1 additional tumor in a population of a million has to be weighed against saving 100 lives from having a phone handy in an emergency. (I'm just making up the numbers here, of course, but you get the point.)

that's pretty simple.. Assume that the tissue has the specific heat of water. 1 Joule will raise the temperature of 1 gram of water about 1/4 degree C..

So, dump 2.55W/kg and you get about 0.0006 degree rise per second. Hang on the phone for, say, 10 minutes (600 seconds) and you'll get a temperature rise of a bit less than 1/2 degree C.

For comparison:
putting your head in sunlight results in an incident flux of about 1kW/square meter (peak). Assuming skin reflectivity of 0.36, the flux being absorbed is about 640W/square meter. Let's assume that the energy is absorbed in the first centimeter of your skin/bone, and that your head is a circle about 10cm in radius (e.g. 314 square centimeters).. That works out to about 20 watts total power being absorbed (compare to the 0.25W RF in the example above). Again, let's say that the density is 1g/cc, so the 20W is being dumped into 0.314 kg, or a SAR of 64 W/kg.

That's a rise of 0.015 degree/second, or 10 degrees in 10 minutes. In reality, you won't see that much rise, because bloodflow carries some of the heat away, and so does convection.

1275. Burying coax idea

Have any of you ever used a gas powered lawn edger to bury a cable/s? I was thinking of trying this. I wonder if I set the edger blade at about 2 " or so deep and took my time if it would work. I need to bury 3 cables from my Direct TV dish and a RG8 coax from my vertical to my house. Please post if you think this would work or have tried it.
Thanks.

I have a pdf of that entire issue. It is about 20Mb and some of it is
still illegible. Let me know if you want me to send it to you. TNX

You "play the odds." You bet that all which is knowledge/in-print is correct--you counsel others to only walk well worn paths. Of course, the odds will bear this out ... it is only that rare event which will produce something revolutionary, useful or provides a path for further exploration, etc. In all your posts, this is the ONE fact which always proves true.

You attempt to "look smart" by poking fun at others attempts to further and refine that which already exists, their speculations/logic/experiments/etc. You find safety in other mens endeavors which have born fruit ...

You have a low self-opinion of yourself (perhaps a correct one!) You, long ago, gave up on the ability of your mind/thinking/experiments to produce anything usable (again, perhaps correct.) You have absolutely nothing to offer except those things thought-of/discovered/experimented-with/documented-by other men, you must protect your ego at all costs--this implies you must NEVER be wrong, at any cost(s) ... you recognize this deficiency in yourself and attempt to convert it into an asset rather than a liability. The energy/stealth and deception/deceit afford you a modicum of success--the general public is easily confused and fooled ...

You think I am the only one to notice these things about you, and much more? I think not, most just don't like arguing with children. Your glass house not only exhibits holes/fractures/breaks, whole panes are missing!

Now, on about your business -- I will be watching and recording, long past all others have grown bored and moved on. There is something morbid and fascinating about such self-inflicted punishment(s) which grabs a minds attention, and pity ... the size of your shoe-box has been seen and duly noted ...

You attempt to make words suggesting caution a directly conflict to some chosen point(s) of yours, a slight-of-hand fitting a grade school student ... as you were soldier, carry on ...

Regards,
JS
